Abstract

Thank you for becoming a part of the FreeBSD Documentation Project. Your contribution is extremely valuable, and we appreciate it.

This primer covers details needed to start contributing to the FreeBSD Documentation Project, or FDP, including tools, software, and the philosophy behind the Documentation Project.

This is a work in progress. Corrections and additions are always welcome.

Preface

1. Shell Prompts

This table shows the default system prompt and superuser prompt. The examples use these prompts to indicate which type of user is running the example.

User	Prompt
Normal user	%
root	#

2. Typographic Conventions

This table describes the typographic conventions used in this book.

Meaning	Examples
The names of commands.	Use <code>ls -l</code> to list all files.
The names of files.	Edit <code>.login</code> .
On-screen computer output.	<code>You have mail.</code>
What the user types, contrasted with on-screen computer output.	<code>% date +"The time is %H:%M"</code> <code>The time is 09:18</code>
Manual page references.	Use <code>su(1)</code> to change user identity.
User and group names.	Only <code>root</code> can do this.
Emphasis.	The user <i>must</i> do this.
Text that the user is expected to replace with the actual text.	To search for a keyword in the manual pages, type <code>man -k keyword</code>
Environment variables.	<code>\$HOME</code> is set to the user's home directory.

3. Notes, Tips, Important Information, Warnings, and Examples

Notes, warnings, and examples appear within the text.

Note

Notes are represented like this, and contain information to take note of, as it may affect what the user does.

Tip

Tips are represented like this, and contain information helpful to the user, like showing an easier way to do something.

Important

Important information is represented like this. Typically, these show extra steps the user may need to take.

Warning

Warnings are represented like this, and contain information warning about possible damage if the instructions are not followed. This damage may be physical, to the hardware or the user, or it may be non-physical, such as the inadvertent deletion of important files.

Example 1. A Sample Example

Examples are represented like this, and typically contain examples showing a walkthrough, or the results of a particular action.

Preface

4. Acknowledgments

My thanks to Sue Blake, Patrick Durusau, Jon Hamilton, Peter Flynn, and Christopher Maden, who took the time to read early drafts of this document and offer many valuable comments and criticisms.

Chapter 1. Overview

Welcome to the FreeBSD Documentation Project (FDP). Quality documentation is crucial to the success of FreeBSD, and we value your contributions very highly.

This document describes how the FDP is organized, how to write and submit documentation, and how to effectively use the available tools.

Everyone is welcome to contribute to the FDP. Willingness to contribute is the only membership requirement.

This primer shows how to:

- Identify which parts of FreeBSD are maintained by the FDP.
- Install the required documentation tools and files.
- Make changes to the documentation.
- Submit changes back for review and inclusion in the FreeBSD documentation.

1.1. The FreeBSD Documentation Set

The FDP is responsible for four categories of FreeBSD documentation.

- *Handbook*: The Handbook is the comprehensive online resource and reference for FreeBSD users.
- *FAQ*: The FAQ uses a short question and answer format to address questions that are frequently asked on the various mailing lists and forums devoted to FreeBSD. This format does not permit long and comprehensive answers.
- *Manual pages*: The English language system manual pages are usually not written by the FDP, as they are part of the base system. However, the FDP can reword parts of existing manual pages to make them clearer or to correct inaccuracies.
- *Web site*: This is the main FreeBSD presence on the web, visible at <http://www.FreeBSD.org/> and many mirrors around the world. The web site is typically a new user's first exposure to FreeBSD.

Translation teams are responsible for translating the Handbook and web site into different languages. Manual pages are not translated at present.

Documentation source for the FreeBSD web site, Handbook, and FAQ is available in the documentation repository at <https://svn.FreeBSD.org/doc/>.

Source for manual pages is available in a separate source repository located at <https://svn.FreeBSD.org/base/> .

Documentation commit messages are visible with `svn log`. Commit messages are also archived at <http://lists.FreeBSD.org/mailman/listinfo/svn-doc-all> .

Web frontends to both of these repositories are available at <https://svnweb.FreeBSD.org/doc/> and <https://svnweb.FreeBSD.org/base/>.

Many people have written tutorials or how-to articles about FreeBSD. Some are stored as part of the FDP files. In other cases, the author has decided to keep the documentation separate. The FDP endeavors to provide links to as much of this external documentation as possible.

1.2. Quick Start

Some preparatory steps must be taken before editing the FreeBSD documentation. First, subscribe to the [FreeBSD documentation project mailing list](#). Some team members also interact on the `#bsddocs` IRC channel on [EFnet](#). These people can help with questions or problems involving the documentation.

1. Install the [textproc/docproj](#) package or port. This meta-port installs all of the software needed to edit and build FreeBSD documentation.
2. Install a local working copy of the documentation from a mirror of the FreeBSD repository in `~/doc` (see [Chapter 3, The Working Copy](#)).

```
% svn checkout https://svn0.us-west.FreeBSD.org/doc/head ~/doc
```

3. Configure the text editor:
 - Word wrap set to 70 characters.
 - Tab stops set to 2.
 - Replace each group of 8 leading spaces with a single tab.

Specific editor configurations are listed in [Chapter 13, Editor Configuration](#).

4. Update the local working copy:

```
% svn up ~/doc
```

5. Edit the documentation files that require changes. If a file needs major changes, consult the mailing list for input.

References to tag and entity usage can be found in [Chapter 8, XHTML Markup](#) and [Chapter 9, DocBook Markup](#).

6. After editing, check for problems by running:

```
% igor -R filename.xml | less -RS
```

Review the output and edit the file to fix any problems shown, then rerun the command to find any remaining problems. Repeat until all of the errors are resolved.

7. Always build-test changes before submitting them. Running **make** in the top-level directory of the documentation being edited will generate that documentation in split HTML format. For example, to build the English version of the Handbook in HTML, run **make** in the `en_US.ISO8859-1/books/handbook/` directory.
8. When changes are complete and tested, generate a “diff file”:

```
% cd /usr/doc  
% svn diff > bsdinstall.diff.txt
```

Give the diff file a descriptive name. In the example above, changes have been made to the `bsdinstall` portion of the Handbook.

9. Submit the diff file using the web-based [Problem Report](#) system or with [send-pr\(1\)](#). If using the web form, enter a synopsis of *[patch] short description of problem*. Select the category `docs` and the class `doc-bug`. In the body of the message, enter a short description of the changes and any important details about them. Use the [\[Browse... \]](#) button to attach the diff file.

Chapter 2. Tools

Several software tools are used to manage the FreeBSD documentation and render it to different output formats. Some of these tools are required and must be installed before working through the examples in the following chapters. Some are optional, adding capabilities or making the job of creating documentation less demanding.

2.1. Required Tools

Install [textproc/docproj](#) from the Ports Collection. This *meta-port* installs all the applications required to do useful work with the FreeBSD documentation. Some further notes on particular components are given below.

2.1.1. DTDs and Entities

FreeBSD documentation uses several Document Type Definitions (DTDs) and sets of XML entities. These are all installed by the [textproc/docproj](#) port.

XHTML DTD ([textproc/xhtmll](#))

XHTML is the markup language of choice for the World Wide Web, and is used throughout the FreeBSD web site.

DocBook DTD ([textproc/docbook-xml-450](#))

DocBook is designed for marking up technical documentation. Most of the FreeBSD documentation is written in DocBook.

ISO 8879 entities ([textproc/iso8879](#))

Character entities from the ISO 8879:1986 standard used by many DTDs. Includes named mathematical symbols, additional characters in the Latin character set (accents, diacriticals, and so on), and Greek symbols.

2.2. Optional Tools

These applications are not required, but can make working on the documentation easier or add capabilities.

2.2.1. Software

JadeTeX, teTeX and Modular DocBook Stylesheets ([print/jadetex](#), [print/teTeX](#) and [textproc/dsssl-docbook-modular](#))

Jade, teTeX and Modular DocBook Stylesheets are used to convert DocBook documents to DVI, Postscript, and PDF formats. The JadeTeX macros are needed to do this.

If XHTML and plain text output formats are adequate, then this program is not needed and the option to install it from the [textproc/docproj](#) configuration screen can be disabled.

Vim ([editors/vim](#))

A popular editor for working with XML and derived documents, like DocBook XML.

Emacs or XEmacs ([editors/emacs](#) or [editors/xemacs](#))

Both of these editors include a special mode for editing documents marked up according to an XML DTD. This mode includes commands to reduce the amount of typing needed, and help reduce the possibility of errors.

Chapter 3. The Working Copy

The *working copy* is a copy of the FreeBSD repository documentation tree downloaded onto the local computer. Changes are made to the local working copy, tested, and then submitted as patches to be committed to the main repository.

A full copy of the documentation tree can occupy 700 megabytes of disk space. Allow for a full gigabyte of space to have room for temporary files and test versions of various output formats.

[Subversion](#) is used to manage the FreeBSD documentation files. It is installed by [textproc/docproj](#) as one of the required applications.

3.1. Documentation and Manual Pages

FreeBSD documentation is not just books and articles. Manual pages for all the commands and configuration files are also part of the documentation, and part of the FDP's territory. Two repositories are involved: `doc` for the books and articles, and `base` for the operating system and manual pages. To edit manual pages, the `base` repository must be checked out separately.

Repositories may contain multiple versions of documentation and source code. New modifications are almost always made only to the latest version, called `head`.

3.2. Choosing a Mirror

To increase speed and reduce download time, select a mirror from the list of [Subversion mirror sites](#) that is close to your location. Substitute the chosen mirror URL for the `https://svn0.us-west.FreeBSD.org/` used in these examples.

3.3. Choosing a Directory

FreeBSD documentation is traditionally stored in `/usr/doc/`, and system source code with manual pages in `/usr/src/`. These directory trees are relocatable, and users may want to put the working copies in other locations to avoid interfering with existing information in the main directories. The examples that follow use `~/doc` and `~/src`, both subdirectories of the user's home directory.

3.4. Checking Out a Copy

A download of a working copy from the repository is called a *checkout*, and done with `svn checkout`. This example checks out a copy of the latest version (*head*) of the main documentation tree:

```
% svn checkout https://svn0.us-west.FreeBSD.org/doc/head ~/doc
```

A checkout of the source code to work on manual pages is very similar:

```
% svn checkout https://svn0.us-west.FreeBSD.org/base/head ~/src
```

3.5. Updating a Working Copy

The documents and files in the FreeBSD repository change daily. People modify files and commit changes frequently. Even a short time after an initial checkout, there will already be differences between the local working copy and the main FreeBSD repository. To update the local version with the changes that have been made to the main repository, use `svn update` on the directory containing the local working copy:

```
% svn update ~/doc
```

Get in the protective habit of using `svn update` before editing document files. Someone else may have edited that file very recently, and the local working copy will not include the latest changes until it has been updated. Editing the newest version of a file is much easier than trying to combine an older, edited local file with the newer version from the repository.

3.6. Reverting Changes

Sometimes it turns out that changes were not necessary after all, or the writer just wants to start over. Files can be “reset” to their unchanged form with `svn revert`. For example, to erase the edits made to `chapter.xml` and reset it to unmodified form:

```
% svn revert chapter.xml
```

3.7. Making a Diff

After edits to a file or group of files are completed, the differences between the local working copy and the version on the FreeBSD repository must be collected into a single file for submission. These *diff* files are produced by redirecting the output of `svn diff` into a file:

```
% cd ~/doc  
% svn diff > doc-fix-spelling.diff
```

Give the file a meaningful name that identifies the contents. The example above is for spelling fixes to the whole documentation tree.

If the diff file is to be submitted with the web “[Submit a FreeBSD problem report](#)” interface, add a `.txt` extension to give the earnest and simple-minded web form a clue that the contents are plain text.

Be careful: `svn diff` includes all changes made in the current directory and any subdirectories. If there are files in the working copy with edits that are not ready to be submitted yet, provide a list of only the files that are to be included:

```
% cd ~/doc
% svn diff disks/chapter.xml printers/chapter.xml > disks-printers.
diff
```

3.8. Subversion References

These examples show very basic usage of Subversion. More detail is available in the [Subversion Book](#) and the [Subversion documentation](#).

Chapter 4. Documentation Directory Structure

Files and directories in the `doc/` tree follow a structure meant to:

1. Make it easy to automate converting the document to other formats.
2. Promote consistency between the different documentation organizations, to make it easier to switch between working on different documents.
3. Make it easy to decide where in the tree new documentation should be placed.

In addition, the documentation tree must accommodate documents in many different languages and encodings. It is important that the documentation tree structure does not enforce any particular defaults or cultural preferences.

4.1. The Top Level, `doc/`

There are two types of directory under `doc/`, each with very specific directory names and meanings.

Directory	Usage
<code>share</code>	Contains files that are not specific to the various translations and encodings of the documentation. Contains subdirectories to further categorize the information. For example, the files that comprise the make(1) infrastructure are in <code>share/mk</code> , while the additional XML support files (such as the FreeBSD extended DocBook DTD) are in <code>share/xml</code> .
<code>lang.encoding</code>	One directory exists for each available translation and encoding of the documentation, for example <code>en_US.ISO8859-1/</code> and <code>zh_TW.UTF-8/</code> . The names are long, but by fully specifying the language and encoding we prevent any future headaches when a translation team wants to provide documentation in the same language but in more than one encoding. This also avoids

Directory	Usage
	problems that might be caused by a future switch to Unicode.

4.2. The *lang.encoding* / Directories

These directories contain the documents themselves. The documentation is split into up to three more categories at this level, indicated by the different directory names.

Directory	Usage
articles	Documentation marked up as a DocBook article (or equivalent). Reasonably short, and broken up into sections. Normally only available as one XHTML file.
books	Documentation marked up as a DocBook book (or equivalent). Book length, and broken up into chapters. Normally available as both one large XHTML file (for people with fast connections, or who want to print it easily from a browser) and as a collection of linked, smaller files.
man	For translations of the system manual pages. This directory will contain one or more <i>man<i>n</i></i> directories, corresponding to the sections that have been translated.

Not every *lang.encoding* directory will have all of these subdirectories. It depends on how much translation has been accomplished by that translation team.

4.3. Document-Specific Information

This section contains specific notes about particular documents managed by the FDP.

4.3.1. The Handbook

books/handbook/

The Handbook is written in DocBook XML using the FreeBSD DocBook extended DTD.

The Handbook is organized as a DocBook book. The book is divided into parts, each of which contains several chapters. chapters are further subdivided into sections (sect1) and subsections (sect2, sect3) and so on.

4.3.1.1. Physical Organization

There are a number of files and directories within the handbook directory.

Note

The Handbook's organization may change over time, and this document may lag in detailing the organizational changes. Post questions about Handbook organization to [FreeBSD documentation project mailing list](#).

4.3.1.1.1. Makefile

The `Makefile` defines some variables that affect how the XML source is converted to other formats, and lists the various source files that make up the Handbook. It then includes the standard `doc.project.mk`, to bring in the rest of the code that handles converting documents from one format to another.

4.3.1.1.2. book.xml

This is the top level document in the Handbook. It contains the Handbook's [DOCTYPE declaration](#), as well as the elements that describe the Handbook's structure.

`book.xml` uses [parameter entities](#) to load in the files with the `.ent` extension. These files (described later) then define [general entities](#) that are used throughout the rest of the Handbook.

4.3.1.1.3. directory/chapter.xml

Each chapter in the Handbook is stored in a file called `chapter.xml` in a separate directory from the other chapters. Each directory is named after the value of the `id` attribute on the `chapter` element.

For example, if one of the chapter files contains:

```
<chapter id="kernelconfig">
...
</chapter>
```

Then it will be called `chapter.xml` in the `kernelconfig` directory. In general, the entire contents of the chapter are in this one file.

When the XHTML version of the Handbook is produced, this will yield `kernelconfig.html`. This is because of the `id` value, and is not related to the name of the directory.

In earlier versions of the Handbook, the files were stored in the same directory as `book.xml`, and named after the value of the `id` attribute on the file's `chapter` element. Now, it is possible to include images in each chapter. Images for each Handbook chapter are stored within `share/images/books/handbook`. The localized version of these images should be placed in the same directory as the XML sources for each chapter. Namespace collisions are inevitable, and it is easier to work with several directories with a few files in them than it is to work with one directory that has many files in it.

A brief look will show that there are many directories with individual `chapter.xml` files, including `basics/chapter.xml`, `introduction/chapter.xml`, and `printing/chapter.xml`.

Important

Do not name chapters or directories after their ordering within the Handbook. This ordering can change as the content within the Handbook is reorganized. Reorganization should be possible without renaming files, unless entire chapters are being promoted or demoted within the hierarchy.

The `chapter.xml` files are not complete XML documents that can be built individually. They can only be built as parts of the whole Handbook.

Chapter 5. The Documentation Build Process

This chapter covers organization of the documentation build process and how [make\(1\)](#) is used to control it.

5.1. The FreeBSD Documentation Build Toolset

These are the tools used to build and install the FDP documentation.

- The primary build tool is [make\(1\)](#), specifically Berkeley Make.
- Package building is handled by FreeBSD's [pkg_create\(1\)](#).
- [gzip\(1\)](#) is used to create compressed versions of the document. [bzip2\(1\)](#) archives are also supported. [tar\(1\)](#) is used for package building.
- [install\(1\)](#) is used to install the documentation.

5.2. Understanding Makefiles in the Documentation Tree

There are three main types of Makefiles in the FreeBSD Documentation Project tree.

- [Subdirectory Makefiles](#) simply pass commands to those directories below them.
- [Documentation Makefiles](#) describe the document(s) that should be produced from this directory.
- [Make includes](#) are the glue that perform the document production, and are usually of the form `doc.xxx.mk`.

5.2.1. Subdirectory Makefiles

These Makefiles usually take the form of:

```
SUBDIR =articles
SUBDIR+=books

COMPAT_SYMLINK = en
```

```
DOC_PREFIX?= ${.CURDIR}/..  
.include "${DOC_PREFIX}/share/mk/doc.project.mk"
```

The first four non-empty lines define the [make\(1\)](#) variables SUBDIR, COMPAT_SYMLINK, and DOC_PREFIX.

The SUBDIR statement and COMPAT_SYMLINK statement show how to assign a value to a variable, overriding any previous value.

The second SUBDIR statement shows how a value is appended to the current value of a variable. The SUBDIR variable is now articles books.

The DOC_PREFIX assignment shows how a value is assigned to the variable, but only if it is not already defined. This is useful if DOC_PREFIX is not where this Makefile thinks it is - the user can override this and provide the correct value.

What does it all mean? SUBDIR mentions which subdirectories below this one the build process should pass any work on to.

COMPAT_SYMLINK is specific to compatibility symlinks (amazingly enough) for languages to their official encoding (doc/en would point to en_US.ISO-8859-1).

DOC_PREFIX is the path to the root of the FreeBSD Document Project tree. This is not always that easy to find, and is also easily overridden, to allow for flexibility. .CURDIR is a [make\(1\)](#) builtin variable with the path to the current directory.

The final line includes the FreeBSD Documentation Project's project-wide [make\(1\)](#) system file doc.project.mk which is the glue which converts these variables into build instructions.

5.2.2. Documentation Makefiles

These Makefiles set [make\(1\)](#) variables that describe how to build the documentation contained in that directory.

Here is an example:

```
MAINTAINER=nik@FreeBSD.org  
  
DOC?= book  
  
FORMATS?= html-split html  
  
INSTALL_COMPRESSED?= gz  
INSTALL_ONLY_COMPRESSED=  
  
# SGML content  
SRCS= book.xml
```

```
DOC_PREFIX?= ${CURDIR}/../..
.include "$(DOC_PREFIX)/share/mk/docproj.docbook.mk"
```

The **MAINTAINER** variable allows committers to claim ownership of a document in the Free-BSD Documentation Project, and take responsibility for maintaining it.

DOC is the name (sans the .xml extension) of the main document created by this directory. SRCS lists all the individual files that make up the document. This should also include important files in which a change should result in a rebuild.

FORMATS indicates the default formats that should be built for this document. INSTALL_COMPRESSED is the default list of compression techniques that should be used in the document build. INSTALL_ONLY_COMPRESS , empty by default, should be non-empty if only compressed documents are desired in the build.

The DOC PREFIX and include statements should be familiar already.

5.3. FreeBSD Documentation Project Make Includes

`make(1)` includes are best explained by inspection of the code. Here are the system include files:

- `doc.project.mk` is the main project include file, which includes all the following include files, as necessary.
- `doc.subdir.mk` handles traversing of the document tree during the build and install processes.
- `doc.install.mk` provides variables that affect ownership and installation of documents.
- `doc.docbook.mk` is included if `DOCFORMAT` is `docbook` and `DOC` is set.

5.3.1. doc.project.mk

By inspection:

```
DOCFORMAT?= docbook
MAINTAINER?= doc@FreeBSD.org

PREFIX?= /usr/local
PRI_LANG?= en_US.ISO8859-1

.if defined(DOC)
.if ${DOCFORMAT} == "docbook"
```

```
.include "doc.docbook.mk"
#endif
#endif

.include "doc.subdir.mk"
.include "doc.install.mk"
```

5.3.1.1. Variables

DOCFORMAT and MAINTAINER are assigned default values, if these are not set by the document make file.

PREFIX is the prefix under which the [documentation building tools](#) are installed. For normal package and port installation, this is `/usr/local`.

PRI_LANG should be set to whatever language and encoding is natural amongst users these documents are being built for. US English is the default.

Note

PRI_LANG does not affect which documents can, or even will, be built. Its main use is creating links to commonly referenced documents into the FreeBSD documentation install root.

5.3.1.2. Conditionals

The `.if defined(DOC)` line is an example of a [make\(1\)](#) conditional which, like in other programs, defines behavior if some condition is true or if it is false. `defined` is a function which returns whether the variable given is defined or not.

`.if ${DOCFORMAT} == "docbook"`, next, tests whether the DOCFORMAT variable is "docbook", and in this case, includes `doc.docbook.mk`.

The two `.endifs` close the two above conditionals, marking the end of their application.

5.3.2. doc.subdir.mk

This file is too long to explain in detail. These notes describe the most important features.

5.3.2.1. Variables

- SUBDIR is a list of subdirectories that the build process should go further down into.
- ROOT_SYMLINKS is the name of directories that should be linked to the document install root from their actual locations, if the current language is the primary language (specified by PRI_LANG).

- `COMPAT_SYMLINK` is described in the [Subdirectory Makefile](#) section.

5.3.2.2. Targets and Macros

Dependencies are described by *target*: *dependency1 dependency2 ...* tuples, where to build *target*, the given dependencies must be built first.

After that descriptive tuple, instructions on how to build the target may be given, if the conversion process between the target and its dependencies are not previously defined, or if this particular conversion is not the same as the default conversion method.

A special dependency `.USE` defines the equivalent of a macro.

```
_SUBDIRUSE: .USE
.for entry in ${SUBDIR}
@${ECHO} "====> ${DIRPRFX}${entry}"
@(cd ${CURDIR}/${entry} && \
 ${MAKE} ${TARGET:S/realpackage/package/:S/realinstall/install/} &
 DIRPRFX=${DIRPRFX}${entry}/ )
.endfor
```

In the above, `_SUBDIRUSE` is now a macro which will execute the given commands when it is listed as a dependency.

What sets this macro apart from other targets? Basically, it is executed *after* the instructions given in the build procedure it is listed as a dependency to, and it does not adjust `.TARGET`, which is the variable which contains the name of the target currently being built.

```
clean: _SUBDIRUSE
rm -f ${CLEANFILES}
```

In the above, `clean` will use the `_SUBDIRUSE` macro after it has executed the instruction `rm -f ${CLEANFILES}`. In effect, this causes `clean` to go further and further down the directory tree, deleting built files as it goes *down*, not on the way back up.

5.3.2.2.1. Provided Targets

- `install` and `package` both go down the directory tree calling the real versions of themselves in the subdirectories (`realinstall` and `realpackage` respectively).
- `clean` removes files created by the build process (and goes down the directory tree too). `cleandir` does the same, and also removes the object directory, if any.

5.3.2.3. More on Conditionals

- `exists` is another condition function which returns true if the given file exists.
- `empty` returns true if the given variable is empty.
- `target` returns true if the given target does not already exist.

5.3.2.4. Looping Constructs in `make` (`.for`)

`.for` provides a way to repeat a set of instructions for each space-separated element in a variable. It does this by assigning a variable to contain the current element in the list being examined.

```
_SUBDIRUSE: .USE
.for entry in ${SUBDIR}
  @${ECHO} "==> ${DIRPRFX}${entry}"
  @(cd ${.CURDIR}/${entry} && \
    ${MAKE} ${.TARGET:S/realpackage/package/:S/realinstall/install/} ǃ
  DIRPRFX=${DIRPRFX}${entry}/ )
.endfor
```

In the above, if `SUBDIR` is empty, no action is taken; if it has one or more elements, the instructions between `.for` and `.endfor` would repeat for every element, with `entry` being replaced with the value of the current element.

Chapter 6. The Website

6.1. Build the Web Pages

Having obtained the documentation and web site source files, the web site can be built. In this example, the build directory is `~/doc` and all the required files are already in place.

The web site is built from the `en_US.IS08859-1/htdocs` subdirectory of the document tree directory, `~/doc` in this example. Change to the build directory and start the build by executing `make all`.

```
% cd ~/doc/en_US.IS08859-1/htdocs
% make all
```

Tip

The web site build uses the `INDEX` from the Ports Collection and may fail if that file or `/usr/ports` is not present. The simplest approach is to install the [Ports Collection](#).

6.2. Install the Web Pages

Run `make install`, setting `DESTDIR` to the target directory for the web site files. The files will be installed in `$DESTDIR/data`, which is expected to be the web server's document root.

This installation is run as the `root` user because the permissions on the web server directory will not allow files to be installed by an unprivileged user. In this example, the web site files were built by user `jru` in their home directory, `/usr/home/jru/doc`.

```
# cd /home/jru/doc/en_US.IS08859-1/htdocs
# env DESTDIR=/usr/local/www make install
```

The install process will not delete any old or outdated files that existed previously in the same directory. If a new copy of the site is built and installed every day, this command will find and delete all files that have not been updated in three days.

```
# find /usr/local/www -ctime 3 -delete
```

6.3. Environment Variables

ENGLISH_ONLY

If set and not empty, only the English documents will be built or installed. All translations will be ignored. E.g.:

```
# make ENGLISH_ONLY=YES all install
```

To unset the variable and build all pages, including translations, set `ENGLISH_ONLY` to an empty value:

```
# make ENGLISH_ONLY="" all install clean
```

WEB_ONLY

If set and not empty, only the HTML pages from the `en_US.ISO8859-1/htdocs` directory will be built or installed. All other directories within `en_US.ISO8859-1` (Handbook, FAQ, Tutorials) will be ignored. E.g.:

```
# make WEB_ONLY=YES all install
```

WEB_LANG

If set, build or install only for the languages specified by this variable inside the `~/doc` directory. All other languages except English will be ignored. E.g.:

```
# make WEB_LANG="el_GR.ISO8859-7 es_ES.ISO8859-1 hu_HU.ISO8859-2 &nl_NL.ISO8859-1" all install
```

`WEB_ONLY`, `WEB_LANG`, and `ENGLISH_ONLY` are [make\(1\)](#) variables and can be set in `/etc/make.conf`, `Makefile.inc`, as environment variables on the command line, or in dot files.

Chapter 7. XML Primer

Most FDP documentation is written with markup languages based on XML. This chapter explains what that means, how to read and understand the documentation source, and the XML techniques used.

Portions of this section were inspired by Mark Galassi's [Get Going With DocBook](#).

7.1. Overview

In the original days of computers, electronic text was simple. There were a few character sets like ASCII or EBCDIC, but that was about it. Text was text, and what you saw really was what you got. No frills, no formatting, no intelligence.

Inevitably, this was not enough. When text is in a machine-usable format, machines are expected to be able to use and manipulate it intelligently. Authors want to indicate that certain phrases should be emphasized, or added to a glossary, or made into hyperlinks. Filenames could be shown in a “typewriter” style font for viewing on screen, but as “italics” when printed, or any of a myriad of other options for presentation.

It was once hoped that Artificial Intelligence (AI) would make this easy. The computer would read the document and automatically identify key phrases, filenames, text that the reader should type in, examples, and more. Unfortunately, real life has not happened quite like that, and computers still require assistance before they can meaningfully process text.

More precisely, they need help identifying what is what. Consider this text:

To remove /tmp/foo , use `rm(1)`.

```
% rm /tmp/foo
```

It is easy to see which parts are filenames, which are commands to be typed in, which parts are references to manual pages, and so on. But the computer processing the document cannot. For this we need markup.

“Markup” is commonly used to describe “adding value” or “increasing cost”. The term takes on both these meanings when applied to text. Markup is additional text included in the document, distinguished from the document's content in some way, so that programs that process the document can read the markup and use it when making decisions about the document. Editors can hide the markup from the user, so the user is not distracted by it.

The extra information stored in the markup *adds value* to the document. Adding the markup to the document must typically be done by a person—after all, if computers could

recognize the text sufficiently well to add the markup then there would be no need to add it in the first place. This *increases the cost* (the effort required) to create the document.

The previous example is actually represented in this document like this:

```
<para>To remove <filename> /tmp/foo</filename> , use &man.rm.1;.</para>  
<screen>&prompt.user; <userinput> rm /tmp/foo</userinput> </screen>
```

The markup is clearly separate from the content.

Markup languages define what the markup means and how it should be interpreted.

Of course, one markup language might not be enough. A markup language for technical documentation has very different requirements than a markup language that is intended for cookery recipes. This, in turn, would be very different from a markup language used to describe poetry. What is really needed is a first language used to write these other markup languages. A *meta markup language*.

This is exactly what the eXtensible Markup Language (XML) is. Many markup languages have been written in XML, including the two most used by the FDP, XHTML and DocBook.

Each language definition is more properly called a grammar, vocabulary, schema or Document Type Definition (DTD). There are various languages to specify an XML grammar, or *schema*.

A schema is a *complete* specification of all the elements that are allowed to appear, the order in which they should appear, which elements are mandatory, which are optional, and so forth. This makes it possible to write an XML *parser* which reads in both the schema and a document which claims to conform to the schema. The parser can then confirm whether or not all the elements required by the vocabulary are in the document in the right order, and whether there are any errors in the markup. This is normally referred to as “validating the document”.

Note

Validation confirms that the choice of elements, their ordering, and so on, conforms to that listed in the grammar. It does *not* check whether *appropriate* markup has been used for the content. If all the filenames in a document were marked up as function names, the parser would not flag this as an error (assuming, of course, that the schema defines elements for filenames and functions, and that they are allowed to appear in the same place).

Most contributions to the Documentation Project will be content marked up in either XHTML or DocBook, rather than alterations to the schemas. For this reason, this book will not touch on how to write a vocabulary.

7.2. Elements, Tags, and Attributes

All the vocabularies written in XML share certain characteristics. This is hardly surprising, as the philosophy behind XML will inevitably show through. One of the most obvious manifestations of this philosophy is that of *content* and *elements*.

Documentation, whether it is a single web page, or a lengthy book, is considered to consist of content. This content is then divided and further subdivided into elements. The purpose of adding markup is to name and identify the boundaries of these elements for further processing.

For example, consider a typical book. At the very top level, the book is itself an element. This “book” element obviously contains chapters, which can be considered to be elements in their own right. Each chapter will contain more elements, such as paragraphs, quotations, and footnotes. Each paragraph might contain further elements, identifying content that was direct speech, or the name of a character in the story.

It may be helpful to think of this as “chunking” content. At the very top level is one chunk, the book. Look a little deeper, and there are more chunks, the individual chapters. These are chunked further into paragraphs, footnotes, character names, and so on.

Notice how this differentiation between different elements of the content can be made without resorting to any XML terms. It really is surprisingly straightforward. This could be done with a highlighter pen and a printout of the book, using different colors to indicate different chunks of content.

Of course, we do not have an electronic highlighter pen, so we need some other way of indicating which element each piece of content belongs to. In languages written in XML (XHTML, DocBook, et al) this is done by means of *tags*.

A tag is used to identify where a particular element starts, and where the element ends. *The tag is not part of the element itself.* Because each grammar was normally written to mark up specific types of information, each one will recognize different elements, and will therefore have different names for the tags.

For an element called *element-name* the start tag will normally look like `<element-name>`. The corresponding closing tag for this element is `</element-name>`.

Example 7.1. Using an Element (Start and End Tags)

XHTML has an element for indicating that the content enclosed by the element is a paragraph, called `p`.

```
<p>This is a paragraph. It starts with the start tag for  
the 'p' element, and it will end with the end tag for the 'p'  
element.</p>  
  
<p>This is another paragraph. But this one is much shorter.</  
p>
```

Some elements have no content. For example, in XHTML, a horizontal line can be included in the document. For these “empty” elements, XML introduced a shorthand form that is completely equivalent to the two-tag version:

Example 7.2. Using an Element Without Content

XHTML has an element for indicating a horizontal rule, called `hr`. This element does not wrap content, so it looks like this:

```
<p>One paragraph.</p>  
<hr></hr>  
  
<p>This is another paragraph. A horizontal rule separates this  
from the previous paragraph.</p>
```

The shorthand version consists of a single tag:

```
<p>One paragraph.</p>  
<hr/>  
  
<p>This is another paragraph. A horizontal rule separates this  
from the previous paragraph.</p>
```

As shown above, elements can contain other elements. In the book example earlier, the book element contained all the chapter elements, which in turn contained all the paragraph elements, and so on.

Example 7.3. Elements Within Elements; `em`

```
<p>This is a simple <em>paragraph</em> where some  
of the <em>words</em> have been <em>emphasized</em>.</p>
```

The grammar consists of rules that describe which elements can contain other elements, and exactly what they can contain.

Important

People often confuse the terms tags and elements, and use the terms as if they were interchangeable. They are not.

An element is a conceptual part of your document. An element has a defined start and end. The tags mark where the element starts and ends.

When this document (or anyone else knowledgeable about XML) refers to “the `<p>` tag” they mean the literal text consisting of the three characters `<`, `p`, and `>`. But the phrase “the `p` element” refers to the whole element.

This distinction is very subtle. But keep it in mind.

Elements can have attributes. An attribute has a name and a value, and is used for adding extra information to the element. This might be information that indicates how the content should be rendered, or might be something that uniquely identifies that occurrence of the element, or it might be something else.

An element's attributes are written *inside* the start tag for that element, and take the form `attribute-name="attribute-value "`.

In XHTML, the `p` element has an attribute called `align`, which suggests an alignment (justification) for the paragraph to the program displaying the XHTML.

The `align` attribute can take one of four defined values, `left`, `center`, `right` and `justify`. If the attribute is not specified then the default is `left`.

Example 7.4. Using an Element with an Attribute

```
<p align="left"> The inclusion of the align attribute
  on this paragraph was superfluous, since the default is to
  left.</p>

<p align="center"> This may appear in the center.</p>
```

Some attributes only take specific values, such as `left` or `justify`. Others allow any value.

Example 7.5. Single Quotes Around Attributes

```
<p align='right'> I am on the right!</p>
```

Attribute values in XML must be enclosed in either single or double quotes. Double quotes are traditional. Single quotes are useful when the attribute value contains double quotes.

Information about attributes, elements, and tags is stored in catalog files. The Documentation Project uses standard DocBook catalogs and includes additional catalogs for FreeBSD-specific features. Paths to the catalog files are defined in an environment variable so they can be found by the document build tools.

7.2.1. To Do...

Before running the examples in this document, install [textproc/docproj](#) from the FreeBSD Ports Collection. This is a *meta-port* that downloads and installs the standard programs and supporting files needed by the Documentation Project. [csh\(1\)](#) users must use `rehash` for the shell to recognize new programs after they have been installed, or log out and then log back in again.

1. Create `example.xml`, and enter this text:

```
<!DOCTYPE html PUBLIC "-//W3C//DTD XHTML 1.0 Transitional//EN"
  "http://www.w3.org/TR/xhtml1/DTD/xhtml1-transitional.dtd">

<html xmlns="http://www.w3.org/1999/xhtml">
  <head>
    <title>An Example XHTML File</title>
  </head>
```

```
<body>
  <p>This is a paragraph containing some text.</p>

  <p>This paragraph contains some more text.</p>

  <p align="right"> This paragraph might be right-justified.</p>
</body>
</html>
```

2. Try to validate this file using an XML parser.

[textproc/docproj](#) includes the `xmllint` [validating parser](#) [24].

Use `xmllint` to validate the document:

```
% xmllint --valid --noout example.xml
```

`xmllint` returns without displaying any output, showing that the document validated successfully.

3. See what happens when required elements are omitted. Delete the line with the `<title>` and `</title>` tags, and re-run the validation.

```
% xmllint --valid --noout example.xml
example.xml:5: element head: validity error : Element head ␣
content does not follow the DTD, expecting ((script | style | meta
| link | object | isindex)* , ((title , (script | style | meta
| link | object | isindex)* , (base , (script | style | meta | ␣
link | object | isindex)*?) | (base , (script | style | meta | ␣
link | object | isindex)* , title , (script | style | meta | link
| object | isindex)*))), got (
```

This shows that the validation error comes from the *fifth* line of the *example.xml* file and that the content of the `<head>` is the part which does not follow the rules of the XHTML grammar.

Then `xmllint` shows the line where the error was found and marks the exact character position with a `^` sign.

4. Replace the title element.

7.3. The DOCTYPE Declaration

The beginning of each document can specify the name of the DTD to which the document conforms. This DOCTYPE declaration is used by XML parsers to identify the DTD and ensure that the document does conform to it.

A typical declaration for a document written to conform with version 1.0 of the XHTML DTD looks like this:

```
<!DOCTYPE html PUBLIC "-//W3C//DTD XHTML 1.0 Transitional//EN"
"http://www.w3.org/TR/xhtml1/DTD/xhtml1-transitional.dtd">
```

That line contains a number of different components.

<!

The *indicator* shows this is an XML declaration.

DOCTYPE

Shows that this is an XML declaration of the document type.

html

Names the first [element](#) that will appear in the document.

```
PUBLIC "-//W3C//DTD XHTML 1.0 Transitional//EN" "http://www.w3.org/TR/
xhtml1/DTD/xhtml1-transitional.dtd"
```

Lists the Formal Public Identifier (FPI) for the DTD to which this document conforms. The XML parser uses this to find the correct DTD when processing this document.

PUBLIC is not a part of the FPI, but indicates to the XML processor how to find the DTD referenced in the FPI. Other ways of telling the XML parser how to find the DTD are shown [later](#).

```
"http://www.w3.org/TR/xhtml1/DTD/xhtml1-transitional.dtd"
```

A local filename or a URL to find the DTD.

>

Ends the declaration and returns to the document.

7.3.1. Formal Public Identifiers (FPIs)

Note

It is not necessary to know this, but it is useful background, and might help debug problems when the XML processor can not locate the DTD.

FPIs must follow a specific syntax:

```
"Owner//Keyword Description //Language "
```

Owner

The owner of the FPI.

The beginning of the string identifies the owner of the FPI. For example, the FPI "ISO 8879:1986//ENTITIES Greek Symbols//EN" lists ISO 8879:1986 as being the owner for the set of entities for Greek symbols. ISO 8879:1986 is the International Organization for Standardization (ISO) number for the SGML standard, the predecessor (and a superset) of XML.

Otherwise, this string will either look like `-//Owner` or `+//Owner` (notice the only difference is the leading + or -).

If the string starts with - then the owner information is unregistered, with a + identifying it as registered.

ISO 9070:1991 defines how registered names are generated. It might be derived from the number of an ISO publication, an ISBN code, or an organization code assigned according to ISO 6523. Additionally, a registration authority could be created in order to assign registered names. The ISO council delegated this to the American National Standards Institute (ANSI).

Because the FreeBSD Project has not been registered, the owner string is `-//FreeBSD`. As seen in the example, the W3C are not a registered owner either.

Keyword

There are several keywords that indicate the type of information in the file. Some of the most common keywords are DTD, ELEMENT, ENTITIES, and TEXT. DTD is used only for DTD files, ELEMENT is usually used for DTD fragments that contain only entity or element declarations. TEXT is used for XML content (text and tags).

Description

Any description can be given for the contents of this file. This may include version numbers or any short text that is meaningful and unique for the XML system.

Language

An ISO two-character code that identifies the native language for the file. EN is used for English.

7.3.1.1. catalog Files

With the syntax above, an XML processor needs to have some way of turning the FPI into the name of the file containing the DTD. A catalog file (typically called `catalog`) contains lines that map FPIs to filenames. For example, if the catalog file contained the line:

```
PUBLIC "-//W3C//DTD XHTML 1.0 Transitional//EN" "1.0/
transitional.dtd"
```

The XML processor knows that the DTD is called `transitional.dtd` in the `1.0` subdirectory of the directory that held `catalog`.

Examine the contents of `/usr/local/share/xml/dtd/xhtml/catalog.xml`. This is the catalog file for the XHTML DTDs that were installed as part of the [textproc/docproj](#) port.

7.3.2. Alternatives to FPIs

Instead of using an FPI to indicate the DTD to which the document conforms (and therefore, which file on the system contains the DTD), the filename can be explicitly specified.

The syntax is slightly different:

```
<!DOCTYPE html SYSTEM "/path/to/file.dtd">
```

The SYSTEM keyword indicates that the XML processor should locate the DTD in a system specific fashion. This typically (but not always) means the DTD will be provided as a filename.

Using FPIs is preferred for reasons of portability. If the SYSTEM identifier is used, then the DTD must be provided and kept in the same location for everyone.

7.4. Escaping Back to XML

Some of the underlying XML syntax can be useful within documents. For example, comments can be included in the document, and will be ignored by the parser. Comments are entered using XML syntax. Other uses for XML syntax will be shown later.

XML sections begin with a `<!` tag and end with a `>`. These sections contain instructions for the parser rather than elements of the document. Everything between these tags is XML syntax. The [DOCTYPE declaration](#) shown earlier is an example of XML syntax included in the document.

7.5. Comments

Comments are an XML construct, and are normally only valid inside a DTD. However, as [Section 7.4, “Escaping Back to XML”](#) shows, it is possible to use XML syntax within the document.

The delimiter for XML comments is the string `--`. The first occurrence of this string opens a comment, and the second closes it.

Example 7.6. XML Generic Comment

```
<!-- This is inside the comment -->
```

```
<!-- This is another comment -->

<!-- This is one way
      of doing multiline comments -->

<!-- This is another way of --
      -- doing multiline comments -->
```

XHTML users may be familiar with different rules for comments. In particular, it is often believed that the string `<!--` opens a comment, and it is only closed by `-->`.

This is *not* correct. Many web browsers have broken XHTML parsers, and will accept incorrect input as valid. However, the XML parsers used by the Documentation Project are more strict, and will reject documents with that error.

Example 7.7. Erroneous XML Comments

```
<!-- This is in the comment --
      THIS IS OUTSIDE THE COMMENT!
-- back inside the comment -->
```

The XML parser will treat this as though it were actually:

```
<!THIS IS OUTSIDE THE COMMENT>
```

That is not valid XML, and may give confusing error messages.

7.5.1. To Do...

1. Add some comments to `example.xml`, and check that the file still validates using `xmllint`.
2. Add some invalid comments to `example.xml`, and see the error messages that `xmllint` gives when it encounters an invalid comment.

7.6. Entities

Entities are a mechanism for assigning names to chunks of content. As an XML parser processes a document, any entities it finds are replaced by the content of the entity.

This is a good way to have re-usable, easily changeable chunks of content in XML documents. It is also the only way to include one marked up file inside another using XML.

There are two types of entities for two different situations: *general entities* and *parameter entities*.

7.6.1. General Entities

General entities are used to assign names to reusable chunks of text. These entities can only be used in the document. They cannot be used in an XML context.

To include the text of a general entity in the document, include `&entity-name`; in the text. For example, consider a general entity called `current.version` which expands to the current version number of a product. To use it in the document, write:

```
<para>The current version of our product is  
&current.version;.</para>
```

When the version number changes, edit the definition of the general entity, replacing the value. Then reprocess the document.

General entities can also be used to enter characters that could not otherwise be included in an XML document. For example, `<` and `&` cannot normally appear in an XML document. The XML parser sees the `<` symbol as the start of a tag. Likewise, when the `&` symbol is seen, the next text is expected to be an entity name.

These symbols can be included by using two predefined general entities: `<` and `&`.

General entities can only be defined within an XML context. Such definitions are usually done immediately after the DOCTYPE declaration.

Example 7.8. Defining General Entities

```
<!DOCTYPE html PUBLIC "-//W3C//DTD XHTML 1.0 Transitional//EN"  
"http://www.w3.org/TR/xhtml1/DTD/xhtml1-transitional.dtd" [  
  <!ENTITY current.version    "3.0-RELEASE">  
  <!ENTITY last.version      "2.2.7-RELEASE">  
>
```

The DOCTYPE declaration has been extended by adding a square bracket at the end of the first line. The two entities are then defined over the next two lines, the square bracket is closed, and then the DOCTYPE declaration is closed.

The square brackets are necessary to indicate that the DTD indicated by the DOCTYPE declaration is being extended.

7.6.2. Parameter Entities

Parameter entities, like [general entities](#), are used to assign names to reusable chunks of text. But parameter entities can only be used within an [XML context](#).

Parameter entity definitions are similar to those for general entities. However, parameter entries are included with `%entity-name`; . The definition also includes the % between the ENTITY keyword and the name of the entity.

For a mnemonic, think “Parameter entities use the Percent symbol”.

Example 7.9. Defining Parameter Entities

```
<!DOCTYPE html PUBLIC "-//W3C//DTD XHTML 1.0 Transitional//EN"
"http://www.w3.org/TR/xhtml1/DTD/xhtml1-transitional.dtd" [
  <!ENTITY % param.some "some">
  <!ENTITY % param.text "text">
  <!ENTITY % param.new "%param.some more %param.text">

  <!-- %param.new now contains "some more text" -->
]>
```

7.6.3. To Do...

1. Add a general entity to example.xml .

```
<!DOCTYPE html PUBLIC "-//W3C//DTD XHTML 1.0 Transitional//EN"
"http://www.w3.org/TR/xhtml1/DTD/xhtml1-transitional.dtd" [
  <!ENTITY version "1.1">
]>

<html xmlns="http://www.w3.org/1999/xhtml">
  <head>
    <title>An Example XHTML File</title>
  </head>

  <!-- There may be some comments in here as well -->

  <body>
    <p>This is a paragraph containing some text.</p>

    <p>This paragraph contains some more text.</p>

    <p align="right"> This paragraph might be right-justified.</p>

    <p>The current version of this document is: &version;</p>
```

```
</body>
</html>
```

2. Validate the document using `xmllint`.
3. Load `example.xml` into a web browser. It may have to be copied to `example.html` before the browser recognizes it as an XHTML document.

Older browsers with simple parsers may not render this file as expected. The entity reference `&version;` may not be replaced by the version number, or the XML context closing `<` may not be recognized and instead shown in the output.

4. The solution is to *normalize* the document with an XML normalizer. The normalizer reads valid XML and writes equally valid XML which has been transformed in some way. One way the normalizer transforms the input is by expanding all the entity references in the document, replacing the entities with the text that they represent.

`xmllint` can be used for this. It also has an option to drop the initial DTD section so that the closing `<` does not confuse browsers:

```
% xmllint --noent --dropdtd example.xml > example.html
```

A normalized copy of the document with entities expanded is produced in `example.html`, ready to load into a web browser.

7.7. Using Entities to Include Files

Both [general](#) and [parameter](#) entities are particularly useful for including one file inside another.

7.7.1. Using General Entities to Include Files

Consider some content for an XML book organized into files, one file per chapter, called `chapter1.xml`, `chapter2.xml`, and so forth, with a `book.xml` that will contain these chapters.

In order to use the contents of these files as the values for entities, they are declared with the `SYSTEM` keyword. This directs the XML parser to include the contents of the named file as the value of the entity.

Example 7.10. Using General Entities to Include Files

```
<!DOCTYPE html PUBLIC "-//W3C//DTD XHTML 1.0 Transitional//EN"
"http://www.w3.org/TR/xhtml1/DTD/xhtml1-transitional.dtd" [
```

```

<!ENTITY chapter.1 SYSTEM "chapter1.xml">
<!ENTITY chapter.2 SYSTEM "chapter2.xml">
<!ENTITY chapter.3 SYSTEM "chapter3.xml">
<!-- And so forth -->
]>

<html xmlns="http://www.w3.org/1999/xhtml">
  <!-- Use the entities to load in the chapters -->

  &chapter.1;
  &chapter.2;
  &chapter.3;
</html>

```

Warning

When using general entities to include other files within a document, the files being included (chapter1.xml , chapter2.xml , and so on) *must not* start with a DOCTYPE declaration. This is a syntax error because entities are low-level constructs and they are resolved before any parsing happens.

7.7.2. Using Parameter Entities to Include Files

Parameter entities can only be used inside an XML context. Including a file in an XML context can be used to ensure that general entities are reusable.

Suppose that there are many chapters in the document, and these chapters were reused in two different books, each book organizing the chapters in a different fashion.

The entities could be listed at the top of each book, but that quickly becomes cumbersome to manage.

Instead, place the general entity definitions inside one file, and use a parameter entity to include that file within the document.

Example 7.11. Using Parameter Entities to Include Files

Place the entity definitions in a separate file called chapters.ent and containing this text:

```

<!ENTITY chapter.1 SYSTEM "chapter1.xml">

```

```
<!ENTITY chapter.2 SYSTEM "chapter2.xml">
<!ENTITY chapter.3 SYSTEM "chapter3.xml">
```

Create a parameter entity to refer to the contents of the file. Then use the parameter entity to load the file into the document, which will then make all the general entities available for use. Then use the general entities as before:

```
<!DOCTYPE html PUBLIC "-//W3C//DTD XHTML 1.0 Transitional//EN"
"http://www.w3.org/TR/xhtml1/DTD/xhtml1-transitional.dtd" [
  <!-- Define a parameter entity to load in the chapter general &
  entities -->
  <!ENTITY % chapters SYSTEM "chapters.ent">

  <!-- Now use the parameter entity to load in this file -->
  %chapters;
]>

<html xmlns="http://www.w3.org/1999/xhtml">
  &chapter.1;
  &chapter.2;
  &chapter.3;
</html>
```

7.7.3. To Do...

7.7.3.1. Use General Entities to Include Files

1. Create three files, para1.xml , para2.xml , and para3.xml .

Put content like this in each file:

```
<p>This is the first paragraph.</p>
```

2. Edit example.xml so that it looks like this:

```
<!DOCTYPE html PUBLIC "-//W3C//DTD XHTML 1.0 Transitional//EN"
"http://www.w3.org/TR/xhtml1/DTD/xhtml1-transitional.dtd" [
  <!ENTITY version "1.1">
  <!ENTITY para1 SYSTEM "para1.xml">
  <!ENTITY para2 SYSTEM "para2.xml">
  <!ENTITY para3 SYSTEM "para3.xml">
]>

<html xmlns="http://www.w3.org/1999/xhtml">
  <head>
    <title>An Example XHTML File</title>
  </head>

  <body>
```

```
<p>The current version of this document is: &version;</p>

&para1;
&para2;
&para3;
</body>
</html>
```

3. Produce `example.html` by normalizing `example.xml` .

```
% xmllint --dropdtd --noent example.xml > example.html
```

4. Load `example.html` into the web browser and confirm that the `para n .xml` files have been included in `example.html` .

7.7.3.2. Use Parameter Entities to Include Files

Note

The previous steps must have completed before this step.

1. Edit `example.xml` so that it looks like this:

```
<!DOCTYPE html PUBLIC "-//W3C//DTD XHTML 1.0 Transitional//EN"
"http://www.w3.org/TR/xhtml1/DTD/xhtml1-transitional.dtd" [
<!ENTITY % entities SYSTEM "entities.ent"> %entities;
]>

<html xmlns="http://www.w3.org/1999/xhtml">
  <head>
    <title>An Example XHTML File</title>
  </head>

  <body>
    <p>The current version of this document is: &version;</p>

    &para1;
    &para2;
    &para3;
  </body>
</html>
```

2. Create a new file called `entities.ent` with this content:

```
<!ENTITY version "1.1">
<!ENTITY para1 SYSTEM "para1.xml">
<!ENTITY para2 SYSTEM "para2.xml">
<!ENTITY para3 SYSTEM "para3.xml">
```

3. Produce `example.html` by normalizing `example.xml` .

```
% xmllint --dropdtd --noent example.xml > example.html
```

4. Load `example.html` into the web browser and confirm that the `paran.xml` files have been included in `example.html` .

7.8. Marked Sections

XML provides a mechanism to indicate that particular pieces of the document should be processed in a special way. These are called “marked sections”.

Example 7.12. Structure of a Marked Section

```
<![KEYWORD [  
    Contents of marked section  
]]>
```

As expected of an XML construct, a marked section starts with `<![`.

The first square bracket begins the marked section.

KEYWORD describes how this marked section is to be processed by the parser.

The second square bracket indicates the start of the marked section's content.

The marked section is finished by closing the two square brackets, and then returning to the document context from the XML context with `>`.

7.8.1. Marked Section Keywords

7.8.1.1. CDATA

These keywords denote the marked sections *content model*, and allow you to change it from the default.

When an XML parser is processing a document, it keeps track of the “content model”.

The content model describes the content the parser is expecting to see and what it will do with that content.

The CDATA content model is one of the most useful.

CDATA is for “Character Data”. When the parser is in this content model, it expects to see only characters. In this model the < and & symbols lose their special status, and will be treated as ordinary characters.

Note

When using CDATA in examples of text marked up in XML, remember that the content of CDATA is not validated. The included text must be checked with other means. For example, the content could be written in another document, validated, and then pasted into the CDATA section.

Example 7.13. Using a CDATA Marked Section

```
<para>Here is an example of how to include some text that ☺
contains
  many <literal>&lt;</literal> and <literal>&amp;</literal>
  symbols. The sample text is a fragment of
  <acronym>XHTML</acronym> . The surrounding text (<para> and
  <programlisting> ) are from DocBook.</para>

<programlisting> <![CDATA[<p>This is a sample that shows some ☺
of the
  elements within <acronym>XHTML</acronym> . Since the angle
  brackets are used so many times, it is simpler to say the ☺
whole
  example is a CDATA marked section than to use the entity ☺
names for
  the left and right angle brackets throughout.</p>

  <ul>
    <li>This is a listitem</li>
    <li>This is a second listitem</li>
    <li>This is a third listitem</li>
  </ul>

  <p>This is the end of the example.</p>]]></programlisting>
```

7.8.1.2. INCLUDE and IGNORE

When the keyword is **INCLUDE**, then the contents of the marked section will be processed. When the keyword is **IGNORE**, the marked section is ignored and will not be processed. It will not appear in the output.

Example 7.14. Using **INCLUDE** and **IGNORE** in Marked Sections

```
<![INCLUDE[
  This text will be processed and included.
]]>

<![IGNORE[
  This text will not be processed or included.
]]>
```

By itself, this is not too useful. Text to be removed from the document could be cut out, or wrapped in comments.

It becomes more useful when controlled by [parameter entities](#), yet this usage is limited to entity files.

For example, suppose that documentation was produced in a hard-copy version and an electronic version. Some extra text is desired in the electronic version content that was not to appear in the hard-copy.

Create an entity file that defines general entities to include each chapter and guard these definitions with a parameter entity that can be set to either **INCLUDE** or **IGNORE** to control whether the entity is defined. After these conditional general entity definitions, place one more definition for each general entity to set them to an empty value. This technique makes use of the fact that entity definitions cannot be overridden but the first definition always takes effect. So the inclusion of the chapter is controlled with the corresponding parameter entity. Set to **INCLUDE**, the first general entity definition will be read and the second one will be ignored. Set to **IGNORE**, the first definition will be ignored and the second one will take effect.

Example 7.15. Using a Parameter Entity to Control a Marked Section

```
<![ENTITY % electronic.copy "INCLUDE">

<![%electronic.copy;[
<![ENTITY chap.preface SYSTEM "preface.xml">
]]>

<![ENTITY chap.preface "">
```

When producing the hard-copy version, change the parameter entity's definition to:

```
<!ENTITY % electronic.copy "IGNORE">
```

7.8.2. To Do...

1. Modify entities.ent to contain the following:

```
<!ENTITY version "1.1">
<!ENTITY % conditional.text "IGNORE">

<![%conditional.text;[
<!ENTITY para1 SYSTEM "para1.xml">
]]>

<!ENTITY para1 "">

<!ENTITY para2 SYSTEM "para2.xml">
<!ENTITY para3 SYSTEM "para3.xml">
```

2. Normalize example.xml and notice that the conditional text is not present in the output document. Set the parameter entity guard to INCLUDE and regenerate the normalized document and the text will appear again. This method makes sense if there are more conditional chunks depending on the same condition. For example, to control generating printed or online text.

7.9. Conclusion

That is the conclusion of this XML primer. For reasons of space and complexity, several things have not been covered in depth (or at all). However, the previous sections cover enough XML to introduce the organization of the FDP documentation.

Chapter 8. XHTML Markup

8.1. Introduction

This chapter describes usage of the XHTML markup language used for the FreeBSD web site.

XHTML is the XML version of the HyperText Markup Language, the markup language of choice on the World Wide Web. More information can be found at <http://www.w3.org/> .

XHTML is used to mark up pages on the FreeBSD web site. It is usually not used to mark up other documentation, since DocBook offers a far richer set of elements from which to choose. Consequently, XHTML pages will normally only be encountered when writing for the web site.

HTML has gone through a number of versions. The XML-compliant version described here is called XHTML. The latest widespread version is XHTML 1.0, available in both *strict* and *transitional* variants.

The XHTML DTDs are available from the Ports Collection in [textproc/xhtml](#). They are automatically installed by the [textproc/docproj](#) port.

Note

This is *not* an exhaustive list of elements, since that would just repeat the documentation for XHTML. The aim is to list those elements most commonly used. Please post questions about elements or uses not covered here to the [FreeBSD documentation project mailing list](#).

Inline Versus Block

In the remainder of this document, when describing elements, *inline* means that the element can occur within a block element, and does not cause a line break. A *block* element, by comparison, will cause a line break (and other processing) when it is encountered.

8.2. Formal Public Identifier (FPI)

There are a number of XHTML FPIs, depending upon the version, or *level* of XHTML to which a document conforms. Most XHTML documents on the FreeBSD web site comply with the transitional version of XHTML 1.0.

```
PUBLIC "-//W3C//DTD XHTML 1.0 Transitional//EN"
```

8.3. Sectional Elements

An XHTML document is normally split into two sections. The first section, called the *head*, contains meta-information about the document, such as its title, the name of the author, the parent document, and so on. The second section, the *body*, contains content that will be displayed to the user.

These sections are indicated with *head* and *body* elements respectively. These elements are contained within the top-level *html* element.

Example 8.1. Normal XHTML Document Structure

```
<html xmlns="http://www.w3.org/1999/xhtml">
  <head>
    <title>The Document's Title </title>
  </head>

  <body>

    ...

  </body>
</html>
```

8.4. Block Elements

8.4.1. Headings

XHTML has tags to denote headings in the document at up to six different levels.

The largest and most prominent heading is *h1*, then *h2*, continuing down to *h6*.

The element's content is the text of the heading.

Example 8.2. h1, h2, and Other Header Tags

Usage:

```
<h1>First section</h1>

<!-- Document introduction goes here -->

<h2>This is the heading for the first section</h2>

<!-- Content for the first section goes here -->

<h3>This is the heading for the first sub-section</h3>

<!-- Content for the first sub-section goes here -->

<h2>This is the heading for the second section</h2>

<!-- Content for the second section goes here -->
```

Generally, an XHTML page should have one first level heading (h1). This can contain many second level headings (h2), which can in turn contain many third level headings. Do not leave gaps in the numbering.

8.4.2. Paragraphs

XHTML supports a single paragraph element, p.

Example 8.3. p

Usage:

```
<p>This is a paragraph. It can contain just about any
other element.</p>
```

8.4.3. Block Quotations

A block quotation is an extended quotation from another document that will appear in a separate paragraph.

Example 8.4. `blockquote`

Usage:

```
<p>A small excerpt from the US Constitution:</p>

<blockquote> We the People of the United States, in Order to ʘ
form
  a more perfect Union, establish Justice, insure domestic
  Tranquility, provide for the common defence, promote the ʘ
general
  Welfare, and secure the Blessings of Liberty to ourselves ʘ
and our
  Posterity, do ordain and establish this Constitution for the
  United States of America.</blockquote>
```

8.4.4. Lists

XHTML can present the user with three types of lists: ordered, unordered, and definition.

Entries in an ordered list will be numbered, while entries in an unordered list will be preceded by bullet points. Definition lists have two sections for each entry. The first section is the term being defined, and the second section is the definition.

Ordered lists are indicated by the `ol` element, unordered lists by the `ul` element, and definition lists by the `dl` element.

Ordered and unordered lists contain listitems, indicated by the `li` element. A listitem can contain textual content, or it may be further wrapped in one or more `p` elements.

Definition lists contain definition terms (`dt`) and definition descriptions (`dd`). A definition term can only contain inline elements. A definition description can contain other block elements.

Example 8.5. `ul` and `ol`

Usage:

```
<p>An unordered list. Listitems will probably be
preceded by bullets.</p>
```

```
<ul>
  <li>First item</li>

  <li>Second item</li>

  <li>Third item</li>
</ul>

<p>An ordered list, with list items consisting of multiple
  paragraphs. Each item (note: not each paragraph) will be
  numbered.</p>

<ol>
  <li><p>This is the first item. It only has one paragraph.</p>
</li>

  <li><p>This is the first paragraph of the second item.</p>

    <p>This is the second paragraph of the second item.</p></li>

  <li><p>This is the first and only paragraph of the third
    item.</p></li>
</ol>
```

Example 8.6. Definition Lists with `dl`

Usage:

```
<dl>
  <dt>Term 1</dt>

  <dd><p>Paragraph 1 of definition 1.</p>

    <p>Paragraph 2 of definition 1.</p></dd>

  <dt>Term 2</dt>

  <dd><p>Paragraph 1 of definition 2.</p></dd>

  <dt>Term 3</dt>

  <dd><p>Paragraph 1 of definition 3.</p></dd>
</dl>
```

8.4.5. Pre-formatted Text

Pre-formatted text is shown to the user exactly as it is in the file. Text is shown in a fixed font. Multiple spaces and line breaks are shown exactly as they are in the file.

Wrap pre-formatted text in the `pre` element.

Example 8.7. `pre`

For example, the `pre` tags could be used to mark up an email message:

```
<pre> From: nik@FreeBSD.org
  To: freebsd-doc@FreeBSD.org
  Subject: New documentation available

  There is a new copy of my primer for contributors to the Ȑ
  FreeBSD
  Documentation Project available at

    &lt;URL:http://people.FreeBSD.org/~nik/primer/index.Ȑ
  html&gt;

  Comments appreciated.

N</pre>
```

Keep in mind that `<` and `&` still are recognized as special characters in pre-formatted text. This is why the example shown had to use `<` instead of `<`. For consistency, `>` was used in place of `>`, too. Watch out for the special characters that may appear in text copied from a plain-text source, like an email message or program code.

8.4.6. Tables

Mark up tabular information using the `table` element. A table consists of one or more table rows (`tr`), each containing one or more cells of table data (`td`). Each cell can contain other block elements, such as paragraphs or lists. It can also contain another table (this nesting can repeat indefinitely). If the cell only contains one paragraph then the `pelement` is not needed.

Example 8.8. Simple Use of `table`

Usage:

```
<p>This is a simple 2x2 table.</p>

<table>
  <tr>
    <td>Top left cell</td>

    <td>Top right cell</td>
  </tr>

  <tr>
    <td>Bottom left cell</td>

    <td>Bottom right cell</td>
  </tr>
</table>
```

A cell can span multiple rows and columns by adding the `rowspan` or `colspan` attributes with values for the number of rows or columns to be spanned.

Example 8.9. Using `rowspan`

Usage:

```
<p>One tall thin cell on the left, two short cells next to
it on the right.</p>

<table>
  <tr>
    <td rowspan="2"> Long and thin</td>
  </tr>

  <tr>
    <td>Top cell</td>

    <td>Bottom cell</td>
  </tr>
</table>
```

Example 8.10. Using `colspan`

Usage:

```

<p>One long cell on top, two short cells below it.</p>

<table>
  <tr>
    <td colspan="2"> Top cell</td>
  </tr>

  <tr>
    <td>Bottom left cell</td>

    <td>Bottom right cell</td>
  </tr>
</table>

```

Example 8.11. Using `rowspan` and `colspan` Together

Usage:

```

<p>On a 3x3 grid, the top left block is a 2x2 set of
  cells merged into one. The other cells are normal.</p>

<table>
  <tr>
    <td colspan="2" rowspan="2"> Top left large cell</td>

    <td>Top right cell</td>
  </tr>

  <tr>
    <!-- Because the large cell on the left merges into
      this row, the first <td> will occur on its
      right -->

    <td>Middle right cell</td>
  </tr>

  <tr>
    <td>Bottom left cell</td>

    <td>Bottom middle cell</td>

    <td>Bottom right cell</td>
  </tr>
</table>

```

8.5. In-line Elements

8.5.1. Emphasizing Information

Two levels of emphasis are available in XHTML, `em` and `strong`. `em` is for a normal level of emphasis and `strong` indicates stronger emphasis.

`em` is typically rendered in italic and `strong` is rendered in bold. This is not always the case, and should not be relied upon. According to best practices, web pages only hold structural and semantical information, and stylesheets are later applied to them. Think of semantics, not formatting, when using these tags.

Example 8.12. `em` and `strong`

Usage:

```
<p><em>This</em> has been emphasized, while  
<strong>this</strong> has been strongly emphasized.</p>
```

8.5.2. Indicating Fixed-Pitch Text

Content that should be rendered in a fixed pitch (typewriter) typeface is tagged with `tt` (for “teletype”).

Example 8.13. `tt`

Usage:

```
<p>Many system settings are stored in  
<tt>/etc</tt>.</p>
```

8.5.3. Links

Note

Links are also inline elements.

8.5.3.1. Linking to Other Documents on the Web

A link points to the URL of a document on the web. The link is indicated with `a`, and the `href` attribute contains the URL of the target document. The content of the element becomes the link, indicated to the user by showing it in a different color or with an underline.

Example 8.14. Using ``

Usage:

```
<p>More information is available at the  
<a href="http://www.&os;.org/"> &os; web site</a>.</p>
```

This link always takes the user to the top of the linked document.

8.5.3.2. Linking to Specific Parts of Documents

To link to a specific point within a document, that document must include an *anchor* at the desired point. Anchors are included by setting the `id` attribute of an element to a name. This example creates an anchor by setting the `id` attribute of a `p` element.

Example 8.15. Creating an Anchor

Usage:

```
<p id="samplepara"> This paragraph can be referenced  
in other links with the name <tt>samplepara</tt>.</p>
```

Links to anchors are similar to plain links, but include a `#` symbol and the anchor's ID at the end of the URL.

Example 8.16. Linking to a Named Part of a Different Document

The `samplepara` example is part of a document called `foo.html`. A link to that specific paragraph in the document is constructed in this example.

```
<p>More information can be found in the  
  <a href="foo.html#samplepara"> sample paragraph</a> of  
  <tt>foo.html</tt>.</p>
```

To link to a named anchor within the same document, omit the document's URL, and just use the # symbol followed by the name of the anchor.

Example 8.17. Linking to a Named Part of the Same Document

The samplepara example resides in this document. To link to it:

```
<p>More information can be found in the  
  <a href="#samplepara"> sample paragraph</a> of this  
  document.</p>
```

Chapter 9. DocBook Markup

9.1. Introduction

This chapter is an introduction to DocBook as it is used for FreeBSD documentation. DocBook is a large and complex markup system, but the subset described here covers the parts that are most widely used for FreeBSD documentation. While a moderate subset is covered, it is impossible to anticipate every situation. Please post questions that this document does not answer to the [FreeBSD documentation project mailing list](#).

DocBook was originally developed by HaL Computer Systems and O'Reilly & Associates to be a Document Type Definition (DTD) for writing technical documentation ¹. Since 1998 it is maintained by the [DocBook Technical Committee](#). As such, and unlike LinuxDoc and XHTML, DocBook is very heavily oriented towards markup that describes *what* something is, rather than describing *how* it should be presented.

The DocBook DTD is available from the Ports Collection in the [textproc/docbook-xml](#) port. It is automatically installed as part of the [textproc/docproj](#) port.

Formal Versus Informal

Some elements may exist in two forms, *formal* and *informal*. Typically, the formal version of the element will consist of a title followed by the informal version of the element. The informal version will not have a title.

Inline Versus Block

In the remainder of this document, when describing elements, *inline* means that the element can occur within a block element, and does not cause a line break. A *block* element, by comparison, will cause a line break (and other processing) when it is encountered.

¹A short history can be found under <http://www.oasis-open.org/docbook/intro.shtml#d0e41>.

9.2. FreeBSD Extensions

The FreeBSD Documentation Project has extended the DocBook DTD with additional elements and entities. These additions serve to make some of the markup easier or more precise.

Throughout the rest of this document, the term “DocBook” is used to mean the FreeBSD-extended DocBook DTD.

Note

Most of these extensions are not unique to FreeBSD, it was just felt that they were useful enhancements for this particular project. Should anyone from any of the other *nix camps (NetBSD, OpenBSD, Linux, ...) be interested in collaborating on a standard DocBook extension set, please contact Documentation Engineering Team [<doceng@FreeBSD.org>](mailto:doceng@FreeBSD.org).

9.2.1. FreeBSD Elements

The additional FreeBSD elements are not (currently) in the Ports Collection. They are stored in the FreeBSD Subversion tree, as head/share/xml/freebsd.dtd.

FreeBSD-specific elements used in the examples below are clearly marked.

9.2.2. FreeBSD Entities

This table shows some of the most useful entities available in the FDP. For a complete list, see the *.ent files in doc/share/xml .

FreeBSD Name Entities		
&os;	FreeBSD	
&os.stable;	FreeBSD-STABLE	
&os.current;	FreeBSD-CURRENT	
Manual Page Entities		
&man.ls.1;	ls(1)	Usage: &man.ls.1; is the manual page for <command>ls</command>.

<code>&man.cp.1;</code>	cp(1)	Usage: The manual page for <code><command>cp</command></code> is <code>&man.cp.1;</code> .
<code>&man.command.sectionnumber</code>	link to command manual page in section sectionnumber	Entities are defined for all the FreeBSD manual pages .

FreeBSD Mailing List Entities

<code>&a.doc;</code>	FreeBSD documentation project mailing list	Usage: A link to the <code>&a.doc;</code> .
<code>&a.questions;</code>	FreeBSD general questions mailing list	Usage: A link to the <code>&a.questions;</code> .
<code>&a.listname ;</code>	link to listname	Entities are defined for all the FreeBSD mailing lists .

FreeBSD Document Link Entities

<code>&url.books.handbook;</code>	http://www.FreeBSD.org/doc/en_US.ISO8859-1/books/handbook	Usage: A link to the <code><link xlink:href="&url.books.handbook;/advanced-networking.html">Advanced Networking</link></code> chapter of the Handbook.
<code>&url.books. bookname ;</code>	relative path to bookname	Entities are defined for all the FreeBSD books .
<code>&url.articles.committers-guide;</code>	http://www.FreeBSD.org/doc/en_US.ISO8859-1/articles/committers-guide	Usage: A link to the <code><link xlink:href="&url.articles.committers-guide;">Committer's Guide</link></code> article.
<code>&url.articles. articlename</code>	relative path to articlename	Entities are defined for all the FreeBSD articles .

Other Operating System Name Entities

<code>&linux;</code>	Linux®	The Linux® operating system.
--------------------------	--------	------------------------------

<code>&unix;</code>	UNIX®	The UNIX® operating system.
<code>&windows;</code>	Windows®	The Windows® operating system.
Miscellaneous Entities		
<code>&prompt.root;</code>	#	The root user prompt.
<code>&prompt.user;</code>	%	A prompt for an unprivileged user.
<code>&postscript;</code>	PostScript®	The PostScript® programming language.
<code>&tex;</code>	TeX	The TeX typesetting language.
<code>&xorg;</code>	Xorg	The Xorg open source X Window System.

9.3. Formal Public Identifier (FPI)

In compliance with the DocBook guidelines for writing FPIs for DocBook customizations, the FPI for the FreeBSD extended DocBook DTD is:

```
PUBLIC "-//FreeBSD//DTD DocBook V4.2-Based Extension//EN"
```

9.4. Document Structure

DocBook allows structuring documentation in several ways. The FreeBSD Documentation Project uses two primary types of DocBook document: the book and the article.

Books are organized into chapters. This is a mandatory requirement. There may be parts between the book and the chapter to provide another layer of organization. For example, the Handbook is arranged in this way.

A chapter may (or may not) contain one or more sections. These are indicated with the `sect1` element. If a section contains another section then use the `sect2` element, and so on, up to `sect5`.

Chapters and sections contain the remainder of the content.

An article is simpler than a book, and does not use chapters. Instead, the content of an article is organized into one or more sections, using the same `sect1` (and `sect2` and so on) elements that are used in books.

The nature of the document being written should be used to determine whether it is best marked up as a book or an article. Articles are well suited to information that does not need to be broken down into several chapters, and that is, relatively speaking, quite short, at up to 20-25 pages of content. Books are best suited to information that can be broken up into several chapters, possibly with appendices and similar content as well.

The [FreeBSD tutorials](#) are all marked up as articles, while this document, the [FAQ](#), and the [Handbook](#) are all marked up as books, for example.

9.4.1. Starting a Book

The content of a book is contained within the book element. As well as containing structural markup, this element can contain elements that include additional information about the book. This is either meta-information, used for reference purposes, or additional content used to produce a title page.

This additional information is contained within `info`.

Example 9.1. Boilerplate `book` with `info`

```
<book>
  <info>
    <title>Your Title Here </title>

    <author>
      <personname>
        <firstname>Your first name </firstname>
        <surname>Your surname </surname>
      </personname>

      <affiliation>
    <address>
      <email>Your email address </email>
    </address>
      </affiliation>
    </author>

    <copyright>
      <year>1998</year>
      <holder role="mailto: your email address ">Your name </
holder>
    </copyright>
```

```

<releaseinfo> $FreeBSD$</releaseinfo>

<abstract>
  <para>Include an abstract of the book's contents here. </
para>
</abstract>
</info>

...
</book>

```

9.4.2. Starting an Article

The content of the article is contained within the `article` element. As well as containing structural markup, this element can contain elements that include additional information about the article. This is either meta-information, used for reference purposes, or additional content used to produce a title page.

This additional information is contained within `info`.

Example 9.2. Boilerplate `article` with `info`

```

<article>
  <info>
    <title>Your title here</title>

    <author>
      <personname>
        <firstname>Your first name</firstname>
        <surname>Your surname</surname>
      </personname>

      <affiliation>
        <address>
          <email>Your email address</email></address>
        </address>
      </affiliation>
    </author>

    <copyright>
      <year>1998</year>
      <holder role="mailto: your email address ">Your name</
holder>
    </copyright>

    <releaseinfo> $FreeBSD$</releaseinfo>
  </info>

```

```
<abstract>
  <para>Include an abstract of the article's contents &
here.</para>
</abstract>
</info>

...

</article>
```

9.4.3. Indicating Chapters

Use `chapter` to mark up your chapters. Each chapter has a mandatory `title`. Articles do not contain chapters, they are reserved for books.

Example 9.3. A Simple Chapter

```
<chapter>
  <title>The Chapter's Title</title>

  ...

</chapter>
```

A chapter cannot be empty; it must contain elements in addition to `title`. If you need to include an empty chapter then just use an empty paragraph.

Example 9.4. Empty Chapters

```
<chapter>
  <title>This is An Empty Chapter</title>

  <para></para>
</chapter>
```

9.4.4. Sections Below Chapters

In books, chapters may (but do not need to) be broken up into sections, subsections, and so on. In articles, sections are the main structural element, and each article must contain

at least one section. Use the `sect n` element. The n indicates the section number, which identifies the section level.

The first `sect n` is `sect1`. You can have one or more of these in a chapter. They can contain one or more `sect2` elements, and so on, down to `sect5`.

Example 9.5. Sections in Chapters

```
<chapter>
  <title>A Sample Chapter</title>

  <para>Some text in the chapter.</para>

  <sect1>
    <title>First Section</title>

    ...
  </sect1>

  <sect1>
    <title>Second Section</title>

    <sect2>
      <title>First Sub-Section</title>

      <sect3>
        <title>First Sub-Sub-Section</title>
      ...
    </sect3>
  </sect2>

  <sect2>
    <title>Second Sub-Section (1.2.2)</title>

    ...
  </sect2>
</sect1>
</chapter>
```

Note

Section numbers are automatically generated and prepended to titles when the document is rendered to an output format. The generated section numbers and titles from the example above will be:

- 1.1. First Section
- 1.2. Second Section
- 1.2.1. First Sub-Section
- 1.2.1.1. First Sub-Sub-Section
- 1.2.2. Second Sub-Section

9.4.5. Subdividing Using `part` Elements

parts introduce another level of organization between book and chapter with one or more parts. This cannot be done in an article.

```
<part>
  <title> Introduction</title>

  <chapter>
    <title> Overview</title>

    ...
  </chapter>

  <chapter>
    <title> What is FreeBSD?</title>

    ...
  </chapter>

  <chapter>
    <title> History</title>

    ...
  </chapter>
</part>
```

9.5. Block Elements

9.5.1. Paragraphs

DocBook supports three types of paragraphs: `formalpara`, `para`, and `simplpara`.

Almost all paragraphs in FreeBSD documentation use `para`. `formalpara` includes a `title` element, and `simplpara` disallows some elements from within `para`. Stick with `para`.

Example 9.6. para

Usage:

```
<para>This is a paragraph. It can contain just about any
other element.</para>
```

Appearance:

This is a paragraph. It can contain just about any other element.

9.5.2. Block Quotations

A block quotation is an extended quotation from another document that should not appear within the current paragraph. These are rarely needed.

Blockquotes can optionally contain a title and an attribution (or they can be left untitled and unattributed).

Example 9.7. blockquote

Usage:

```
<para>A small excerpt from the US Constitution:</para>

<blockquote>
  <title>Preamble to the Constitution of the United States</
title>

  <attribution> Copied from a web site somewhere</attribution>

  <para>We the People of the United States, in Order to form a
more
    perfect Union, establish Justice, insure domestic a
Tranquility,
    provide for the common defence, promote the general a
Welfare, and
    secure the Blessings of Liberty to ourselves and our a
Posterity, do
    ordain and establish this Constitution for the United a
States of
    America.</para>
```

```
</blockquote>
```

Appearance:

A small excerpt from the US Constitution:

Preamble to the Constitution of the United States

We the People of the United States, in Order to form a more perfect Union, establish Justice, insure domestic Tranquility, provide for the common defence, promote the general Welfare, and secure the Blessings of Liberty to ourselves and our Posterity, do ordain and establish this Constitution for the United States of America.

—Copied from a web site somewhere

9.5.3. Tips, Notes, Warnings, Cautions, and Important Information

Extra information may need to be separated from the main body of the text. Typically this is “meta” information of which the user should be aware.

Several types of admonitions are available: `tip`, `note`, `warning`, `caution`, and `important`.

Which admonition to choose depends on the situation. The DocBook documentation suggests:

- `Note` is for information that should be heeded by all readers.
- `Important` is a variation on `Note`.
- `Caution` is for information regarding possible data loss or software damage.
- `Warning` is for information regarding possible hardware damage or injury to life or limb.

Example 9.8. `tip` and `important`

Usage:

```
<tip>
```

```
<para>&os; may reduce stress.</para>
</tip>

<important>
  <para>Please use admonitions sparingly. Too many admonitions
    are visually jarring and can have the opposite of the
    intended effect.</para>
</important>
```

Appearance:

Tip

FreeBSD may reduce stress.

Important

Please use admonitions sparingly. Too many admonitions are visually jarring and can have the opposite of the intended effect.

9.5.4. Examples

Examples can be shown with `example`.

Example 9.9. `example`

Usage:

```
<example>
  <para>Empty files can be created easily:</para>

  <screen>&prompt.user; <userinput> touch file1 file2 file3</
userinput> </screen>
</example>
```

Appearance:

Example 9.10.

Empty files can be created easily:

```
% touch file1 file2 file3
```

9.5.5. Lists and Procedures

Information often needs to be presented as lists, or as a number of steps that must be carried out in order to accomplish a particular goal.

To do this, use `itemizedlist`, `orderedlist`, `variablelist`, or `procedure`. There are other types of list elements in DocBook, but we will not cover them here.

`itemizedlist` and `orderedlist` are similar to their counterparts in HTML, `ul` and `ol`. Each one consists of one or more `listitem` elements, and each `listitem` contains one or more block elements. The `listitem` elements are analogous to HTML's `li` tags. However, unlike HTML, they are required.

Example 9.11. `itemizedlist` and `orderedlist`

Usage:

```
<itemizedlist>
  <listitem>
    <para>This is the first itemized item.</para>
  </listitem>

  <listitem>
    <para>This is the second itemized item.</para>
  </listitem>
</itemizedlist>

<orderedlist>
  <listitem>
    <para>This is the first ordered item.</para>
  </listitem>

  <listitem>
    <para>This is the second ordered item.</para>
  </listitem>
</orderedlist>
```

```
</orderedlist>
```

Appearance:

- This is the first itemized item.
 - This is the second itemized item.
1. This is the first ordered item.
 2. This is the second ordered item.

An alternate and often useful way of presenting information is the `variablelist`. These are lists where each entry has a term and a description. They are well suited for many types of descriptions, and present information in a form that is often easier for the reader than sections and subsections.

A `variablelist` has a title, and then pairs of term and `listitem` entries.

Example 9.12. `variablelist`

Usage:

```
<variablelist>
  <varlistentry>
    <term>Parallel</term>

    <listitem>
      <para>In parallel communications, groups of bits arrive
at the same time over multiple communications
channels.</para>
    </listitem>
  </varlistentry>

  <varlistentry>
    <term>Serial</term>

    <listitem>
      <para>In serial communications, bits arrive one at a
time over a single communications
channel.</para>
    </listitem>
  </varlistentry>
</variablelist>
```

Appearance:

Parallel

In parallel communications, groups of bits arrive at the same time over multiple communications channels.

Serial

In serial communications, bits arrive one at a time over a single communications channel.

A procedure shows a series of steps, which may in turn consist of more steps or substeps. Each step contains block elements and may include an optional title.

Sometimes, steps are not sequential, but present a choice: do *this* or do *that*, but not both. For these alternative choices, use `stepalternatives`.

Example 9.13. `procedure`

Usage:

```
<procedure>
  <step>
    <para>Do this.</para>
  </step>

  <step>
    <para>Then do this.</para>
  </step>

  <step>
    <para>And now do this.</para>
  </step>

  <step>
    <para>Finally, do one of these.</para>

    <stepalternatives>
      <step>
        <para>Go left.</para>
      </step>

      <step>
        <para>Go right.</para>
      </step>
    </stepalternatives>
  </step>
</procedure>
```

Appearance:

1. Do this.
2. Then do this.
3. And now do this.
4. Finally, do one of these:
 - Go left.
 - Go right.

9.5.6. Showing File Samples

Fragments of a file (or perhaps a complete file) are shown by wrapping them in the `programlisting` element.

White space and line breaks within `programlisting` are significant. In particular, this means that the opening tag should appear on the same line as the first line of the output, and the closing tag should appear on the same line as the last line of the output, otherwise spurious blank lines may be included.

Example 9.14. `programlisting`

Usage:

```
<para>When finished, the program will look like  
this:</para>
```

```
<programlisting> #include <stdio.h>;  
  
int  
main(void)  
{  
    printf("hello, world\n");  
}</programlisting>
```

Notice how the angle brackets in the `#include` line need to be referenced by their entities instead of being included literally.

Appearance:

When finished, the program will look like this:

```
#include <stdio.h>

int
main(void)
{
    printf("hello, world\n");
}
```

9.5.7. Callouts

A callout is a visual marker for referring to a piece of text or specific position within an example.

Callouts are marked with the `co` element. Each element must have a unique `id` assigned to it. After the example, include a `calloutlist` that describes each callout.

Example 9.15. `co` and `calloutlist`

```
<para>When finished, the program will look like
this:</para>

<programlisting> #include &lt;stdio.h&gt; <co xml:id="co-ex-
include"/>

int <co xml:id="co-ex-return"/>
main(void)
{
    printf("hello, world\n"); <co xml:id="co-ex-printf"/>
}</programlisting>

<calloutlist>
  <callout arearefs="co-ex-include">
    <para>Includes the standard IO header file.</para>
  </callout>

  <callout arearefs="co-ex-return">
    <para>Specifies that <function>main()</function> returns an
    int.</para>
  </callout>

  <callout arearefs="co-ex-printf">
    <para>The <function>printf()</function> call that writes
    <literal>hello, world</literal> to standard output.</
para>
```

```
</callout>
</calloutlist>
```

Appearance:

When finished, the program will look like this:

```
#include <stdio.h> ❶

int ❷
main(void)
{
    printf("hello, world\n"); ❸
}
```

- ❶ Includes the standard IO header file.
- ❷ Specifies that `main()` returns an int.
- ❸ The `printf()` call that writes `hello, world` to standard output.

9.5.8. Tables

Unlike HTML, DocBook does not need tables for layout purposes, as the stylesheet handles those issues. Instead, just use tables for marking up tabular data.

In general terms (and see the DocBook documentation for more detail) a table (which can be either formal or informal) consists of a `table` element. This contains at least one `tgroup` element, which specifies (as an attribute) the number of columns in this table group. Within the `tablegroup` there is one `thead` element, which contains elements for the table headings (column headings), and one `tbody` which contains the body of the table.

Both `tgroup` and `thead` contain `row` elements, which in turn contain `entry` elements. Each `entry` element specifies one cell in the table.

Example 9.16. `informaltable`

Usage:

```
<informaltable pgwide="1">
  <tgroup cols="2">
    <thead>
      <row>
        <entry>This is Column Head 1</entry>
        <entry>This is Column Head 2</entry>
      </row>
```

```

</thead>

<tbody>
  <row>
<entry>Row 1, column 1</entry>
<entry>Row 1, column 2</entry>
  </row>

  <row>
<entry>Row 2, column 1</entry>
<entry>Row 2, column 2</entry>
  </row>
</tbody>
</tgroup>
</informaltable>

```

Appearance:

This is Column Head 1	This is Column Head 2
Row 1, column 1	Row 1, column 2
Row 2, column 1	Row 2, column 2

Always use the `pgwide` attribute with a value of 1 with the `informaltable` element. A bug in Internet Explorer can cause the table to render incorrectly if this is omitted.

Table borders can be suppressed by setting the `frame` attribute to `none` in the `informaltable` element. For example, `informaltable frame="none"`.

Example 9.17. Tables Where `frame="none"`

Appearance:

This is Column Head 1	This is Column Head 2
Row 1, column 1	Row 1, column 2
Row 2, column 1	Row 2, column 2

9.5.9. Examples for the User to Follow

Examples for the user to follow are often necessary. Typically, these will consist of dialogs with the computer; the user types in a command, the user gets a response back, the user types another command, and so on.

A number of distinct elements and entities come into play here.

screen

Everything the user sees in this example will be on the computer screen, so the next element is `screen`.

Within `screen`, white space is significant.

prompt, `&prompt.root`; and `&prompt.user`;

Some of the things the user will be seeing on the screen are prompts from the computer (either from the operating system, command shell, or application). These should be marked up using `prompt`.

As a special case, the two shell prompts for the normal user and the root user have been provided as entities. To indicate the user is at a shell prompt, use one of `&prompt.root`; and `&prompt.user`; as necessary. They do not need to be inside `prompt`.

Note

`&prompt.root`; and `&prompt.user`; are FreeBSD extensions to DocBook, and are not part of the original DTD.

userinput

When displaying text that the user should type in, wrap it in `userinput` tags. It will be displayed differently than system output text.

Example 9.18. `screen`, `prompt`, and `userinput`

Usage:

```
<screen> &prompt.user; <userinput> ls -l</userinput>
foo1
foo2
foo3
&prompt.user; <userinput> ls -l | grep foo2</userinput>
```

```
foo2
&prompt.user; <userinput> su</userinput>
<prompt>Password: </prompt>
&prompt.root; <userinput> cat foo2</userinput>
This is the file called 'foo2'</screen>
```

Appearance:

```
% ls -l
foo1
foo2
foo3
% ls -l | grep foo2
foo2
% su
Password:
# cat foo2
This is the file called 'foo2'
```

Note

Even though we are displaying the contents of the file `foo2`, it is *not* marked up as `programlisting`. Reserve `programlisting` for showing fragments of files outside the context of user actions.

9.6. In-line Elements

9.6.1. Emphasizing Information

To emphasize a particular word or phrase, use `emphasis`. This may be presented as italic, or bold, or might be spoken differently with a text-to-speech system.

There is no way to change the presentation of the emphasis within the document, no equivalent of HTML's `b` and `i`. If the information being presented is important, then consider presenting it in `important` rather than `emphasis`.

Example 9.19. `emphasis`

Usage:

```
<para>&os; is without doubt <emphasis> the</emphasis>
```

```
premiere &unix;-like operating system for the Intel
architecture.</para>
```

Appearance:

FreeBSD is without doubt *the* premiere UNIX®-like operating system for the Intel architecture.

9.6.2. Acronyms

Many computer terms are *acronyms*, words formed from the first letter of each word in a phrase. Acronyms are marked up into `acronym` elements. It is helpful to the reader when an acronym is defined on the first use, as shown in the example below.

Example 9.20. Acronyms

Usage:

```
<para>Request For Comments (<acronym> RFC</acronym> ) 1149
defined the use of avian carriers for transmission of
Internet Protocol (<acronym> IP</acronym> ) data. The
quantity of <acronym> IP</acronym> data currently
transmitted in that manner is unknown.</para>
```

Appearance:

Request For Comments (RFC) 1149 defined the use of avian carriers for transmission of Internet Protocol (IP) data. The quantity of IP data currently transmitted in that manner is unknown.

9.6.3. Quotations

To quote text from another document or source, or to denote a phrase that is used figuratively, use `quote`. Most of the markup tags available for normal text are also available from within a quote.

Example 9.21. Quotations

Usage:

```
<para>However, make sure that the search does not go beyond the
```

```
<quote>boundary between local and public administration</
quote> ,
as <acronym> RFC</acronym> 1535 calls it.</para>
```

Appearance:

However, make sure that the search does not go beyond the “boundary between local and public administration”, as RFC 1535 calls it.

9.6.4. Keys, Mouse Buttons, and Combinations

To refer to a specific key on the keyboard, use `keycap`. To refer to a mouse button, use `mousebutton`. And to refer to combinations of key presses or mouse clicks, wrap them all in `keycombo`.

`keycombo` has an attribute called `action`, which may be one of `click`, `double-click`, `other`, `press`, `seq`, or `simul`. The last two values denote whether the keys or buttons should be pressed in sequence, or simultaneously.

The stylesheets automatically add any connecting symbols, such as `+`, between the key names, when wrapped in `keycombo`.

Example 9.22. Keys, Mouse Buttons, and Combinations

Usage:

```
<para>To switch to the second virtual terminal, press
<keycombo action="simul"> <keycap>Alt</keycap>
<keycap>F1</keycap> </keycombo> .</para>

<para>To exit <command>vi</command> without saving changes, ␣
type
<keycombo action="seq"> <keycap>Esc</keycap> <keycap>:</keycap>
<keycap>q</keycap> <keycap>!</keycap> </keycombo> .</para>

<para>My window manager is configured so that
<keycombo action="simul"> <keycap>Alt</keycap>
<mousebutton> right</mousebutton>
</keycombo> mouse button is used to move windows.</para>
```

Appearance:

To switch to the second virtual terminal, press Alt+F1.

To exit `vi` without saving changes, type `Esc : q !`.

My window manager is configured so that Alt+right mouse button is used to move windows.

9.6.5. Applications, Commands, Options, and Cites

Both applications and commands are frequently referred to when writing documentation. The distinction between them is that an application is the name of a program or suite of programs that fulfill a particular task. A command is the filename of a program that the user can type and run at a command line.

It is often necessary to show some of the options that a command might take.

Finally, it is often useful to list a command with its manual section number, in the “command(number)” format so common in Unix manuals.

Mark up application names with `application`.

To list a command with its manual section number (which should be most of the time) the DocBook element is `citerefentry`. This will contain a further two elements, `refentrytitle` and `manvolnum`. The content of `refentrytitle` is the name of the command, and the content of `manvolnum` is the manual page section.

This can be cumbersome to write, and so a series of [general entities](#) have been created to make this easier. Each entity takes the form `&man.manual-page.manual-section` ;.

The file that contains these entities is in `doc/share/xml/man-refs.ent` , and can be referred to using this FPI:

```
PUBLIC "-//FreeBSD//ENTITIES DocBook Manual Page Entities//EN"
```

Therefore, the introduction to FreeBSD documentation will usually include this:

```
<!DOCTYPE book PUBLIC "-//FreeBSD//DTD DocBook V4.1-Based Extension//
EN" [

<!ENTITY % man PUBLIC "-//FreeBSD//ENTITIES DocBook Manual Page &
Entities//EN">
%man;

...

]>
```

Use `command` to include a command name “in-line” but present it as something the user should type.

Use `option` to mark up the options which will be passed to a command.

When referring to the same command multiple times in close proximity, it is preferred to use the `&man. command .section ;` notation to markup the first reference and use `command` to markup subsequent references. This makes the generated output, especially HTML, appear visually better.

Example 9.23. Applications, Commands, and Options

Usage:

```
<para><application> Sendmail</application> is the most
widely used Unix mail application.</para>

<para><application> Sendmail</application> includes the
<citrefentry>
  <refentrytitle> sendmail</refentrytitle>
  <manvolnum> 8</manvolnum>
</citrefentry> , &man.mailq.1;, and &man.newaliases.1;
programs.</para>

<para>One of the command line parameters to <citrefentry>
  <refentrytitle> sendmail</refentrytitle>
  <manvolnum> 8</manvolnum>
</citrefentry> , <option> -bp</option> , will display the ⚡
current
status of messages in the mail queue. Check this on the ⚡
command
line by running <command> sendmail -bp</command> .</para>
```

Appearance:

Sendmail is the most widely used Unix mail application.

Sendmail includes the [sendmail\(8\)](#), [mailq\(1\)](#), and [newaliases\(1\)](#) programs.

One of the command line parameters to [sendmail\(8\)](#), `-bp`, will display the current status of messages in the mail queue. Check this on the command line by running `sendmail -bp`.

Note

Notice how the `&man. command .section ;` notation is easier to follow.

9.6.6. Files, Directories, Extensions, Device Names

To refer to the name of a file, a directory, a file extension, or a device name, use `filename`. For directory names, set the `class` attribute to `directory`.

Example 9.24. `filename`

Usage:

```
<para>The source for the Handbook in English is found in
  <filename
    class="directory"> /usr/doc/en_US.ISO8859-1/books/handbook/</
  filename> .
  The main file is called <filename> book.xml</filename> .
  There is also a <filename> Makefile</filename> and a
  number of files with a <filename> .ent</filename> extension.</
para>

<para><filename> kbd0</filename> is the first keyboard detected
  by the system, and appears in
  <filename> /dev</filename> .</para>
```

Appearance:

The source for the Handbook in English is found in `/usr/doc/en_US.ISO8859-1/books/handbook/` . The main file is called `book.xml` . There is also a `Makefile` and a number of files with a `.ent` extension.

`kbd0` is the first keyboard detected by the system, and appears in `/dev` .

9.6.7. The Name of Ports

FreeBSD Extension

These elements are part of the FreeBSD extension to DocBook, and do not exist in the original DocBook DTD.

To include the name of a program from the FreeBSD Ports Collection in the document, use the `package` tag. Since the Ports Collection can be installed in any number of locations, only include the category and the port name; do not include `/usr/ports` .

By default, `package` refers to a binary package. To refer to a port that will be built from source, set the `role` attribute to `port` .

Example 9.25. `package` Tag

Usage:

```
<para>Install the <package> net/wireshark</package> binary
package to view network traffic.</para>
```

```
<para><package role="port"> net/wireshark</package> can also be
built and installed from the Ports Collection.</para>
```

Appearance:

Install the [net/wireshark](#) binary package to view network traffic.

[net/wireshark](#) can also be built and installed from the Ports Collection.

9.6.8. Hosts, Domains, IP Addresses, User Names, Group Names, and Other System Items

FreeBSD Extension

These elements are part of the FreeBSD extension to DocBook, and do not exist in the original DocBook DTD.

Information for “system items” is marked up with `systemitem`. The `class` attribute is used to identify the particular type of information shown.

`class="domainname"`

The text is a domain name, such as `FreeBSD.org` or `ngo.org.uk`. There is no host-name component.

`class="etheraddress"`

The text is an Ethernet MAC address, expressed as a series of 2 digit hexadecimal numbers separated by colons.

`class="fqdomainname"`

The text is a Fully Qualified Domain Name, with both hostname and domain name parts.

`class="ipaddress"`

The text is an IP address, probably expressed as a dotted quad.

class="netmask"

The text is a network mask, which might be expressed as a dotted quad, a hexadecimal string, or as a / followed by a number (CIDR notation).

class="systemname"

With class="systemname" the marked up information is the simple hostname, such as freefall or wcarchive.

class="username"

The text is a username, like root.

class="groupname"

The text is a groupname, like wheel.

Example 9.26. `systemitem` and Classes

Usage:

```
<para>The local machine can always be referred to by the  
  name <systemitem class="systemname"> localhost</systemitem> , ♂  
which will have the IP  
  address <systemitem class="ipaddress"> 127.0.0.1</  
systemitem> .</para>
```

```
<para>The <systemitem class="domainname"> FreeBSD.org</  
systemitem>  
  domain contains a number of different hosts, including  
  <systemitem class="fqdomainname"> freefall.FreeBSD.org</  
systemitem> and  
  <systemitem class="fqdomainname"> bento.FreeBSD.org</  
systemitem> .</para>
```

```
<para>When adding an <acronym> IP</acronym> alias to an  
  interface (using <command> ifconfig</command> )  
  <emphasis> always</emphasis> use a netmask of  
  <systemitem class="netmask"> 255.255.255.255</systemitem> ♂  
(which can  
  also be expressed as  
  <systemitem class="netmask"> 0xffffffff</systemitem> ).</para>
```

```
<para>The <acronym> MAC</acronym> address uniquely identifies  
  every network card in existence. A typical  
  <acronym> MAC</acronym> address looks like  
  <systemitem class="etheraddress"> 08:00:20:87:ef:d0</  
systemitem> .</para>
```

```
<para>To carry out most system administration functions  
  requires logging in as <systemitem class="username"> root</  
systemitem> .</para>
```

Appearance:

The local machine can always be referred to by the name `localhost`, which will have the IP address `127.0.0.1`.

The `FreeBSD.org` domain contains a number of different hosts, including `freefall.FreeBSD.org` and `bento.FreeBSD.org`.

When adding an IP alias to an interface (using `ifconfig`) *always* use a netmask of `255.255.255.255` (which can also be expressed as `0xffffffff`).

The MAC address uniquely identifies every network card in existence. A typical MAC address looks like `08:00:20:87:ef:d0`.

To carry out most system administration functions requires logging in as `root`.

9.6.9. Email Addresses

Email addresses are marked up as `email` elements. In the HTML output format, the wrapped text becomes a hyperlink to the email address. Other output formats that support hyperlinks may also make the email address into a link.

Example 9.27. `email` with a Hyperlink

Usage:

```
<para>An email address that does not actually exist, like  
<email>notreal@example.com</email>, can be used as an  
example.</para>
```

Appearance:

An email address that does not actually exist, like notreal@example.com, can be used as an example.

A FreeBSD-specific extension allows setting the `role` attribute to `noLink` to prevent the creation of the hyperlink to the email address.

Example 9.28. `email` Without a Hyperlink

Usage:

```
<para>Sometimes a link to an email address like
  <email role="nolink"> notreal@example.com</email> is not
  desired.</para>
```

Appearance:

Sometimes a link to an email address like [notreal@example.com](#) is not desired.

9.6.10. Describing Makefiles

FreeBSD Extension

These elements are part of the FreeBSD extension to DocBook, and do not exist in the original DocBook DTD.

Two elements exist to describe parts of Makefiles, `buildtarget` and `varname`.

`buildtarget` identifies a build target exported by a Makefile that can be given as a parameter to `make`. `varname` identifies a variable that can be set (in the environment, on the command line with `make`, or within the Makefile) to influence the process.

Example 9.29. `buildtarget` and `varname`

Usage:

```
<para>Two common targets in a <filename> Makefile</filename>
  are <buildtarget> all</buildtarget> and
  <buildtarget> clean</buildtarget> .</para>
```

```
<para>Typically, invoking <buildtarget> all</buildtarget> will
  rebuild the application, and invoking
  <buildtarget> clean</buildtarget> will remove the temporary
  files (<filename>.o</filename> for example) created by the
  build process.</para>
```

```
<para><buildtarget> clean</buildtarget> may be controlled by a
  number of variables, including <varname> CLOBBER</varname>
  and <varname> RECURSE</varname> .</para>
```

Appearance:

Two common targets in a Makefile are `all` and `clean`.

Typically, invoking `all` will rebuild the application, and invoking `clean` will remove the temporary files (`.o` for example) created by the build process.

`clean` may be controlled by a number of variables, including `CLOBBER` and `RECURSE`.

9.6.11. Literal Text

Literal text, or text which should be entered verbatim, is often needed in documentation. This is text that is excerpted from another file, or which should be copied exactly as shown from the documentation into another file.

Some of the time, `programlisting` will be sufficient to denote this text. But `programlisting` is not always appropriate, particularly when you want to include a portion of a file “in-line” with the rest of the paragraph.

On these occasions, use `literal`.

Example 9.30. `literal`

Usage:

```
<para>The <literal>maxusers 10</literal> line in the kernel
configuration file determines the size of many system
tables, and is
a rough guide to how many simultaneous logins the system
will support.</para>
```

Appearance:

The `maxusers 10` line in the kernel configuration file determines the size of many system tables, and is a rough guide to how many simultaneous logins the system will support.

9.6.12. Showing Items That the User Must Fill In

There will often be times when the user is shown what to do, or referred to a file or command line, but cannot simply copy the example provided. Instead, they must supply some information themselves.

`replaceable` is designed for this eventuality. Use it *inside* other elements to indicate parts of that element's content that the user must replace.

Example 9.31. `replaceable`

Usage:

```
<screen>&prompt.user; <userinput> man <replaceable> command</replaceable> </userinput> </screen>
```

Appearance:

```
% man command
```

`replaceable` can be used in many different elements, including `literal`. This example also shows that `replaceable` should only be wrapped around the content that the user is meant to provide. The other content should be left alone.

Usage:

```
<para>The <literal>maxusers <replaceable> n</replaceable> </literal>
  line in the kernel configuration file determines the size of
  many system
  tables, and is a rough guide to how many simultaneous logins
  the system will
  support.</para>

<para>For a desktop workstation, <literal>32</literal> is a good
  value
  for <replaceable> n</replaceable> .</para>
```

Appearance:

The `maxusers n` line in the kernel configuration file determines the size of many system tables, and is a rough guide to how many simultaneous logins the system will support.

For a desktop workstation, 32 is a good value for *n*.

9.6.13. Showing GUI Buttons

Buttons presented by a graphical user interface are marked with `guibutton`. To make the text look more like a graphical button, brackets and non-breaking spaces are added surrounding the text.

Example 9.32. `guibutton`

Usage:

```
<para>Edit the file, then click  
  <guibutton> [ &nbsp;Save&nbsp; ]</guibutton> to save the  
  changes.</para>
```

Appearance:

Edit the file, then click [Save] to save the changes.

9.6.14. Quoting System Errors

System errors generated by FreeBSD are marked with `errorname`. This indicates the exact error that appears.

Example 9.33. `errorname`

Usage:

```
<screen><errorname>Panic: cannot mount root</errorname></  
screen>
```

Appearance:

```
Panic: cannot mount root
```

9.7. Images

Important

Image support in the documentation is somewhat experimental. The mechanisms described here are unlikely to change, but that is not guaranteed.

To provide conversion between different image formats, the [graphics/ImageMagick](#) port must be installed. This port is not included in the [textproc/docproj](#) meta port, and must be installed separately.

A good example of the use of images is the `doc/en_US.ISO8859-1/articles/vm-design/` document. Examine the files in that directory to see how these elements are used together. Build different output formats to see how the format determines what images are shown in the rendered document.

9.7.1. Image Formats

The following image formats are currently supported. An image file will automatically be converted to bitmap or vector image depending on the output document format.

These are the *only* formats in which images should be committed to the documentation repository.

EPS (Encapsulated Postscript)

Images that are primarily vector based, such as network diagrams, time lines, and similar, should be in this format. These images have a `.eps` extension.

PNG (Portable Network Graphic)

For bitmaps, such as screen captures, use this format. These images have the `.png` extension.

PIC (PIC graphics language)

PIC is a language for drawing simple vector-based figures used in the [pic\(1\)](#) utility. These images have the `.pic` extension.

SCR (SCReen capture)

This format is specific to screenshots of console output. The following command generates an SCR file `shot.scr` from video buffer of `/dev/ttyv0` :

```
# vidcontrol -p < /dev/ttyv0 > shot.scr
```

This is preferable to PNG format for screenshots because the SCR file contains plain text of the command lines so that it can be converted to a PNG image or a plain text depending on the output document format.

Use the appropriate format for each image. Documentation will often have a mix of EPS and PNG images. The `Makefiles` ensure that the correct format image is chosen depending on the output format used. *Do not commit the same image to the repository in two different formats.*

Important

The Documentation Project may eventually switch to using the SVG (Scalable Vector Graphic) format for vector images. However, the current state of SVG capable editing tools makes this impractical.

9.7.2. Image File Locations

Image files can be stored in one of several locations, depending on the document and image:

- In the same directory as the document itself, usually done for articles and small books that keep all their files in a single directory.
- In a subdirectory of the main document. Typically done when a large book uses separate subdirectories to organize individual chapters.

When images are stored in a subdirectory of the main document directory, the subdirectory name must be included in their paths in the `Makefile` and the `imagedata` element.

- In a subdirectory of `doc/share/images` named after the document. For example, images for the Handbook are stored in `doc/share/images/books/handbook`. Images that work for multiple translations are stored in this upper level of the documentation file tree. Generally, these are images that can be used unchanged in non-English translations of the document.

9.7.3. Image Markup

Images are included as part of a `mediaobject`. The `mediaobject` can contain other, more specific objects. We are concerned with two, the `imageobject` and the `textobject`.

Include one `imageobject`, and two `textobject` elements. The `imageobject` will point to the name of the image file without the extension. The `textobject` elements contain information that will be presented to the user as well as, or instead of, the image itself.

Text elements are shown to the reader in several situations. When the document is viewed in HTML, text elements are shown while the image is loading, or if the mouse pointer is hovered over the image, or if a text-only browser is being used. In formats like plain text where graphics are not possible, the text elements are shown instead of the graphical ones.

This example shows how to include an image called `fig1.png` in a document. The image is a rectangle with an A inside it:

```

<mediaobject>
  <imageobject>
    <imagedata fileref="fig1"> ❶
  </imageobject>

  <textobject>
    <literallayout class="monospaced"> +-----+ ❷
    |      A      |
    +-----+</literallayout>
  </textobject>

  <textobject>
    <phrase> A picture</phrase> ❸
  </textobject>
</mediaobject>

```

- ❶ Include an `imagedata` element inside the `imageobject` element. The `fileref` attribute should contain the filename of the image to include, without the extension. The stylesheets will work out which extension should be added to the filename automatically.
- ❷ The first `textobject` contains a `literallayout` element, where the `class` attribute is set to `monospaced`. This is an opportunity to demonstrate ASCII art skills. This content will be used if the document is converted to plain text.

Notice how the first and last lines of the content of the `literallayout` element butt up next to the element's tags. This ensures no extraneous white space is included.

- ❸ The second `textobject` contains a single `phrase` element. The contents of this phrase will become the `alt` attribute for the image when this document is converted to HTML.

9.7.4. Image Makefile Entries

Images must be listed in the Makefile in the `IMAGES` variable. This variable must contain the names of all the *source* images. For example, if there are three figures, `fig1.eps`, `fig2.png`, `fig3.png`, then the Makefile should have lines like this in it.

```

...
IMAGES= fig1.eps fig2.png fig3.png
...

```

or

```

...
IMAGES=  fig1.eps
IMAGES+= fig2.png
IMAGES+= fig3.png
...

```

Again, the Makefile will work out the complete list of images it needs to build the source document, you only need to list the image files *you* provided.

9.7.5. Images and Chapters in Subdirectories

Be careful when separating documentation into smaller files in different directories (see [Section 7.7.1, “Using General Entities to Include Files”](#)).

Suppose there is a book with three chapters, and the chapters are stored in their own directories, called `chapter1/chapter.xml`, `chapter2/chapter.xml`, and `chapter3/chapter.xml`. If each chapter has images associated with it, place those images in each chapter's subdirectory (`chapter1/`, `chapter2/`, and `chapter3/`).

However, doing this requires including the directory names in the `IMAGES` variable in the `Makefile`, *and* including the directory name in the `imagedata` element in the document.

For example, if the book has `chapter1/fig1.png`, then `chapter1/chapter.xml` should contain:

```
<mediaobject>
  <imageobject>
    <imagedata fileref="chapter1/fig1"/> ❶
  </imageobject>

  ...

</mediaobject>
```

❶ The directory name must be included in the `fileref` attribute.

The `Makefile` must contain:

```
...
IMAGES= chapter1/fig1.png
...
```

9.8. Links

Note

Links are also in-line elements.

9.8.1. `xml:id` Attributes

Most DocBook elements accept an `xml:id` attribute to give that part of the document a unique name. The `xml:id` can be used as a target for a crossreference or link.

Any portion of the document that will be a link target must have an `xml:id` attribute. Assigning an `xml:id` to all chapters and sections, even if there are no current plans to link to them, is a good idea. These `xml:ids` can be used as unique anchor reference points by anyone referring to the HTML version of the document.

Example 9.34. `xml:id` on Chapters and Sections

```
<chapter xml:id="introduction">
  <title>Introduction</title>

  <para>This is the introduction. It contains a subsection,
    which is identified as well.</para>

  <sect1 xml:id="introduction-moredetails">
    <title>More Details</title>

    <para>This is a subsection.</para>
  </sect1>
</chapter>
```

Use descriptive values for `xml:id` names. The values must be unique within the entire document, not just in a single file. In the example, the subsection `xml:id` is constructed by appending text to the chapter `xml:id`. This ensures that the `xml:ids` are unique. It also helps both reader and anyone editing the document to see where the link is located within the document, similar to a directory path to a file.

To allow the user to jump into a specific portion of the document, even in the middle of a paragraph or an example, use `anchor`. This element has no content, but takes an `xml:id` attribute.

Example 9.35. `anchor`

```
<para>This paragraph has an embedded
  <anchor xml:id="para1"/> link target in it. It will not
  show up in the document.</para>
```

9.8.2. Crossreferences with `xref`

`xref` provides the reader with a link to jump to another section of the document. The target `xml:id` is specified in the `linkend` attribute, and `xref` generates the link text automatically.

Example 9.36. Using `xref`

Assume that this fragment appears somewhere in a document that includes the `xml:id` example shown above:

```
<para>More information can be found  
  in <xref linkend="introduction"/> .</para>  
  
<para>More specific information can be found  
  in <xref linkend="introduction-moredetails"/> .</para>
```

The link text will be generated automatically, looking like (*emphasized text indicates the link text*):

More information can be found in *Chapter 1, Introduction*.

More specific information can be found in *Section 1.1, “More Details”*.

The link text is generated automatically from the chapter and section number and title elements.

Note

`xref` cannot link to an `xml:id` attribute on an anchor element. The anchor has no content, so the `xref` cannot generate the link text.

9.8.3. Linking to the Same Document or Other Documents on the Web

The link elements described here allow the writer to define the link text. It is very important to use descriptive link text to give the reader an idea of where the link will take them. Remember that DocBook can be rendered to multiple types of media. The reader may be looking at a printed book or other form of media where there are no links. If the link text is not descriptive enough, the reader may not be able to locate the linked section.

9.8.3.1. Links to the Same Document

`link` is used to create a link within the same document. The target `xml:id` is specified in the `linkend` attribute. This element wraps content, which is used for the link text.

Example 9.37. Using `link`

Assume that this fragment appears somewhere in a document that includes the `xml:id` example.

```
<para>More information can be found in the
  <link linkend="introduction"> sample introduction</link> .</
para>

<para>More specific information can be found in the
  <link linkend="introduction-moredetails"> sample &
introduction with more
  details</link> section.</para>
```

This output will be generated (*emphasized* text is used to show the link text):

More information can be found in the *sample introduction*.

More specific information can be found in the *sample introduction with more details* section.

Note

`link` can be used to include links to the `xml:id` of an anchor element, since the `link` content defines the link text.

9.8.3.2. Linking to Other Documents on the Web

The `ulink` is used to link to external documents on the web. The `url` attribute is the URL of the page that the link points to, and the content of the element is the text that will be displayed for the user to activate.

Example 9.38. `ulink` to a FreeBSD Documentation Web Page

Link to the book or article URL entity. To link to a specific chapter in a book, add a slash and the chapter file name, followed by an optional anchor within the chap-

ter. For articles, link to the article URL entity, followed by an optional anchor within the article. URL entities can be found in `doc/share/xml/urls.ent` .

Usage for book links:

```
<para>Read the <link
  xlink:href="&url.books.handbook;/svn.html#svn-intro">  SVN
  introduction</link> , then pick the nearest mirror from
  the list of <link
    xlink:href="&url.books.handbook;/svn.html#svn-
    mirrors"> Subversion
    mirror sites</link> .</para>
```

Appearance:

Read the [SVN introduction](#), then pick the nearest mirror from the list of [Subversion mirror sites](#).

Usage for article links:

```
<para>Read this
  <link xlink:href="&url.articles.bsd-gpl;">  article
    about the BSD license</link> , or just the
  <link xlink:href="&url.articles.bsd-
  gpl;#intro"> introduction</link> .</para>
```

Appearance:

Read this [article about the BSD license](#), or just the [introduction](#).

Example 9.39. `link` to a FreeBSD Web Page

Usage:

```
<para>Of course, you could stop reading this document and go o
to the
  <link xlink:href="&url.base;/index.html">  FreeBSD home page</
link> instead.</para>
```

Appearance:

Of course, you could stop reading this document and go to the [FreeBSD home page](#) instead.

Example 9.40. `u`link to an External Web Page

Usage:

```
<para>Wikipedia has an excellent reference on  
  <link  
    xlink:href="http://en.wikipedia.org/wiki/  
GUID_Partition_Table"> GUID  
  Partition Tables</link> .</para>
```

Appearance:

Wikipedia has an excellent reference on [GUID Partition Tables](http://en.wikipedia.org/wiki/GUID_Partition_Table).

The link text can be omitted to show the actual URL:

```
<para>Wikipedia has an excellent reference on  
  GUID Partition Tables: <link  
    xlink:href="http://en.wikipedia.org/wiki/  
GUID_Partition_Table"> </link> .</para>
```

Appearance:

Wikipedia has an excellent reference on GUID Partition Tables: http://en.wikipedia.org/wiki/GUID_Partition_Table .

Chapter 10. Style Sheets

XML is concerned with content, and says nothing about how that content should be presented to the reader or rendered on paper. Multiple *style sheet* languages have been developed to describe visual layout, including Extensible Stylesheet Language Transformation (XSLT), Document Style Semantics and Specification Language (DSSSL), and Cascading Style Sheets (CSS).

The FDP documents use XSLT stylesheets to transform DocBook into XHTML, and then CSS formatting is applied to the XHTML pages. Printable output is currently rendered with legacy DSSSL stylesheets, but this will probably change in the future.

10.1. CSS

Cascading Style Sheets (CSS) are a mechanism for attaching style information (font, weight, size, color, and so forth) to elements in an XHTML document without abusing XHTML to do so.

10.1.1. The DocBook Documents

The FreeBSD XSLT and DSSSL stylesheets refer to `docbook.css`, which is expected to be present in the same directory as the XHTML files. The project-wide CSS file is copied from `doc/share/misc/docbook.css` when documents are converted to XHTML, and is installed automatically.

Chapter 11. Translations

This is the FAQ for people translating the FreeBSD documentation (FAQ, Handbook, tutorials, manual pages, and others) to different languages.

It is *very* heavily based on the translation FAQ from the FreeBSD German Documentation Project, originally written by Frank Gründer <elwood@mc5sys.in-berlin.de> and translated back to English by Bernd Warken <bwarken@mayn.de>.

The FAQ is maintained by the Documentation Engineering Team <doceng@FreeBSD.org>.

Q: Why a FAQ?

A: More and more people are approaching the freebsd-doc mailing list and volunteering to translate FreeBSD documentation to other languages. This FAQ aims to answer their questions so they can start translating documentation as quickly as possible.

Q: What do i18n and l10n mean?

A: i18n means internationalization and l10n means localization. They are just a convenient shorthand.

i18n can be read as “i” followed by 18 letters, followed by “n”. Similarly, l10n is “l” followed by 10 letters, followed by “n”.

Q: Is there a mailing list for translators?

A: Yes. Different translation groups have their own mailing lists. The [list of translation projects](#) has more information about the mailing lists and web sites run by each translation project.

Q: Are more translators needed?

A: Yes. The more people work on translation the faster it gets done, and the faster changes to the English documentation are mirrored in the translated documents.

You do not have to be a professional translator to be able to help.

Q: What languages do I need to know?

A: Ideally, you will have a good knowledge of written English, and obviously you will need to be fluent in the language you are translating to.

English is not strictly necessary. For example, you could do a Hungarian translation of the FAQ from the Spanish translation.

Q: What software do I need to know?

- A: It is strongly recommended that you maintain a local copy of the FreeBSD Subversion repository (at least the documentation part). This can be done by running:

```
% svn checkout https://svn0.us-east.FreeBSD.org /doc/head/ head
```

svn0.us-east.FreeBSD.org is a public SVN server. Select the closest mirror and verify the mirror server certificate from the list of [Subversion mirror sites](#).

Note

This will require the [devel/subversion](#) package to be installed.

You should be comfortable using `svn`. This will allow you to see what has changed between different versions of the files that make up the documentation.

For example, to view the differences between revisions `r33733` and `r33734` of `en_US.IS08859-1/books/fdp-primer/book.xml`, run:

```
% svn diff -r 33733:33734 en_US.IS08859-1/books/fdp-primer/book.xml
```

- Q: How do I find out who else might be translating to the same language?
- A: The [Documentation Project translations page](#) lists the translation efforts that are currently known about. If others are already working on translating documentation to your language, please do not duplicate their efforts. Instead, contact them to see how you can help.

If no one is listed on that page as translating for your language, then send a message to the [FreeBSD documentation project mailing list](#) in case someone else is thinking of doing a translation, but has not announced it yet.

- Q: No one else is translating to my language. What do I do?
- A: Congratulations, you have just started the “FreeBSD *your-language-here* Documentation Translation Project”. Welcome aboard.

First, decide whether or not you have got the time to spare. Since you are the only person working on your language at the moment it is going to be your responsibility to publicize your work and coordinate any volunteers that might want to help you.

Write an email to the Documentation Project mailing list, announcing that you are going to translate the documentation, so the Documentation Project translations page can be maintained.

If there is already someone in your country providing FreeBSD mirroring services you should contact them and ask if you can have some webspace for your project, and possibly an email address or mailing list services.

Then pick a document and start translating. It is best to start with something fairly small—either the FAQ, or one of the tutorials.

Q: I have translated some documentation, where do I send it?

A: That depends. If you are already working with a translation team (such as the Japanese team, or the German team) then they will have their own procedures for handling submitted documentation, and these will be outlined on their web pages.

If you are the only person working on a particular language (or you are responsible for a translation project and want to submit your changes back to the FreeBSD project) then you should send your translation to the FreeBSD project (see the next question).

Q: I am the only person working on translating to this language, how do I submit my translation?

or

We are a translation team, and want to submit documentation that our members have translated for us.

A: First, make sure your translation is organized properly. This means that it should drop into the existing documentation tree and build straight away.

Currently, the FreeBSD documentation is stored in a top level directory called `head/`. Directories below this are named according to the language code they are written in, as defined in ISO639 (`/usr/share/misc/iso639` on a version of FreeBSD newer than 20th January 1999).

If your language can be encoded in different ways (for example, Chinese) then there should be directories below this, one for each encoding format you have provided.

Finally, you should have directories for each document.

For example, a hypothetical Swedish translation might look like:

```
head/
  sv_SE.ISO8859-1/
    Makefile
    htdocs/
      docproj/
    books/
      faq/
        Makefile
```

`sv_SE.IS08859-1` is the name of the translation, in *lang.encoding* form. Note the two Makefiles, which will be used to build the documentation.

Use [tar\(1\)](#) and [gzip\(1\)](#) to compress up your documentation, and send it to the project.

```
% cd doc
% tar cf swedish-docs.tar sv_SE.IS08859-1
% gzip -9 swedish-docs.tar
```

Put `swedish-docs.tar.gz` somewhere. If you do not have access to your own web-space (perhaps your ISP does not let you have any) then you can email Documentation Engineering Team [<doceng@FreeBSD.org>](mailto:doceng@FreeBSD.org), and arrange to email the files when it is convenient.

Either way, you should use [send-pr\(1\)](#) to submit a report indicating that you have submitted the documentation. It would be very helpful if you could get other people to look over your translation and double check it first, since it is unlikely that the person committing it will be fluent in the language.

Someone (probably the Documentation Project Manager, currently Documentation Engineering Team [<doceng@FreeBSD.org>](mailto:doceng@FreeBSD.org)) will then take your translation and confirm that it builds. In particular, the following things will be looked at:

1. Do all your files use RCS strings (such as "ID")?
2. Does `make all` in the `sv_SE.IS08859-1` directory work correctly?
3. Does `make install` work correctly?

If there are any problems then whoever is looking at the submission will get back to you to work them out.

If there are no problems your translation will be committed as soon as possible.

Q: Can I include language or country specific text in my translation?

A: We would prefer that you did not.

For example, suppose that you are translating the Handbook to Korean, and want to include a section about retailers in Korea in your Handbook.

There is no real reason why that information should not be in the English (or German, or Spanish, or Japanese, or ...) versions as well. It is feasible that an English speaker in Korea might try to pick up a copy of FreeBSD whilst over there. It also helps increase FreeBSD's perceived presence around the globe, which is not a bad thing.

If you have country specific information, please submit it as a change to the English Handbook (using [send-pr\(1\)](#)) and then translate the change back to your language in the translated Handbook.

Thanks.

Q: How should language specific characters be included?

A: Non-ASCII characters in the documentation should be included using SGML entities.

Briefly, these look like an ampersand (&), the name of the entity, and a semi-colon (;).

The entity names are defined in ISO8879, which is in the ports tree as [textproc/iso8879](#).

A few examples include:

Entity: é

Appearance: é

Description: Small “e” with an acute accent

Entity: É

Appearance: É

Description: Large “E” with an acute accent

Entity: ü

Appearance: ü

Description: Small “u” with an umlaut

After you have installed the iso8879 port, the files in `/usr/local/share/xml/iso8879` contain the complete list.

Q: Addressing the reader

A: In the English documents, the reader is addressed as “you”, there is no formal/informal distinction as there is in some languages.

If you are translating to a language which does distinguish, use whichever form is typically used in other technical documentation in your language. If in doubt, use a mildly polite form.

Q: Do I need to include any additional information in my translations?

A: Yes.

The header of the English version of each document will look something like this:

```
<!--  
  The FreeBSD Documentation Project
```

```
$FreeBSD: head/en_US.ISO8859-1/books/faq/book.xml 38674 ␣
2012-04-14 13:52:52Z $
-->
```

The exact boilerplate may change, but it will always include a `$FreeBSD$` line and the phrase `The FreeBSD Documentation Project`. Note that the `$FreeBSD` part is expanded automatically by Subversion, so it should be empty (just `$FreeBSD$`) for new files.

Your translated documents should include their own `$FreeBSD$` line, and change the `FreeBSD Documentation Project` line to `The FreeBSD language Documentation Project`.

In addition, you should add a third line which indicates which revision of the English text this is based on.

So, the Spanish version of this file might start:

```
<!--
    The FreeBSD Spanish Documentation Project

    $FreeBSD: head/es_ES.ISO8859-1/books/faq/book.xml 38826 ␣
2012-05-17 19:12:14Z hrs $
    Original revision: r38674
-->
```

Chapter 12. Writing Style

12.1. Tips

Technical documentation can be improved by consistent use of several principles. Most of these can be classified into three goals: *be clear*, *be complete*, and *be concise*. These goals can conflict with each other. Good writing consists of a balance between them.

12.1.1. Be Clear

Clarity is extremely important. The reader may be a novice, or reading the document in a second language. Strive for simple, uncomplicated text that clearly explains the concepts.

Avoid flowery or embellished speech, jokes, or colloquial expressions. Write as simply and clearly as possible. Simple text is easier to understand and translate.

Keep explanations as short, simple, and clear as possible. Avoid empty phrases like “in order to”, which usually just means “to”. Avoid potentially patronizing words like “basically”. Avoid Latin terms like “i.e.” or “cf.”, which may be unknown outside of academic or scientific groups.

Write in a formal style. Avoid addressing the reader as “you”. For example, say “copy the file to /tmp” rather than “you can copy the file to /tmp”.

Give clear, correct, *tested* examples. A trivial example is better than no example. A good example is better yet. Do not give bad examples, identifiable by apologies or sentences like “but really it should never be done that way”. Bad examples are worse than no examples. Give good examples, because *even when warned not to use the example as shown*, the reader will usually just use the example as shown.

Avoid *weasel words* like “should”, “might”, “try”, or “could”. These words imply that the speaker is unsure of the facts, and create doubt in the reader.

Similarly, give instructions as imperative commands: not “you should do this”, but merely “do this”.

12.1.2. Be Complete

Do not make assumptions about the reader's abilities or skill level. Tell them what they need to know. Give links to other documents to provide background information without having to recreate it. Put yourself in the reader's place, anticipate the questions they will ask, and answer them.

12.1.3. Be Concise

While features should be documented completely, sometimes there is so much information that the reader cannot easily find the specific detail needed. The balance between being complete and being concise is a challenge. One approach is to have an introduction, then a “quick start” section that describes the most common situation, followed by an in-depth reference section.

12.2. Guidelines

To promote consistency between the myriad authors of the FreeBSD documentation, some guidelines have been drawn up for authors to follow.

Use American English Spelling

There are several variants of English, with different spellings for the same word. Where spellings differ, use the American English variant. “color”, not “colour”, “rationalize”, not “rationalise”, and so on.

Note

The use of British English may be accepted in the case of a contributed article, however the spelling must be consistent within the whole document. The other documents such as books, web site, manual pages, etc. will have to use American English.

Do not use contractions

Do not use contractions. Always spell the phrase out in full. “Don't use contractions” is wrong.

Avoiding contractions makes for a more formal tone, is more precise, and is slightly easier for translators.

Use the serial comma

In a list of items within a paragraph, separate each item from the others with a comma. Separate the last item from the others with a comma and the word “and”.

For example:

This is a list of one, two and three items.

Is this a list of three items, “one”, “two”, and “three”, or a list of two items, “one” and “two and three”?

It is better to be explicit and include a serial comma:

This is a list of one, two, and three items.

Avoid redundant phrases

Do not use redundant phrases. In particular, “the command”, “the file”, and “man command” are often redundant.

For example, commands:

Wrong: Use the command `svn` to update sources.

Right: Use `svn` to update sources.

Filenames:

Wrong: ... in the filename `/etc/rc.local` ...

Right: ... in `/etc/rc.local` ...

Manual page references (the second example uses `citerefentry` with the `&man.csh.1`; entity):

Wrong: See `man csh` for more information.

Right: See [csh\(1\)](#).

Two spaces between sentences

Always use two spaces between sentences, as it improves readability and eases use of tools such as Emacs.

A period and spaces followed by a capital letter does not always mark a new sentence, especially in names. “Jordan K. Hubbard” is a good example. It has a capital H following a period and a space, and is certainly not a new sentence.

For more information about writing style, see [Elements of Style](#), by William Strunk.

12.3. Style Guide

To keep the source for the documentation consistent when many different people are editing it, please follow these style conventions.

12.3.1. Letter Case

Tags are entered in lower case, `para`, *not* `PARA`.

Text that appears in SGML contexts is generally written in upper case, `<!ENTITY...>`, and `<!DOCTYPE...>`, *not* `<!entity...>` and `<!doctype...>`.

12.3.2. Acronyms

Acronyms should be defined the first time they appear in a document, as in: “Network Time Protocol (NTP)”. After the acronym has been defined, use the acronym alone unless it makes more sense contextually to use the whole term. Acronyms are usually defined only once per chapter or per document.

All acronyms should be enclosed in `acronym` tags.

12.3.3. Indentation

The first line in each file starts with no indentation, *regardless* of the indentation level of the file which might contain the current file.

Opening tags increase the indentation level by two spaces. Closing tags decrease the indentation level by two spaces. Blocks of eight spaces at the start of a line should be replaced with a tab. Do not use spaces in front of tabs, and do not add extraneous white-space at the end of a line. Content within elements should be indented by two spaces if the content runs over more than one line.

For example, the source for this section looks like this:

```
<chapter>
  <title> ...</title>

  <sect1>
    <title> ...</title>

    <sect2>
      <title> Indentation</title>

      <para>The first line in each file starts with no indentation,
<emphasis> regardless</emphasis> of the indentation level of
the file which might contain the current file.</para>

      ...
    </sect2>
  </sect1>
</chapter>
```

Tags containing long attributes follow the same rules. Following the indentation rules in this case helps editors and writers see which content is inside the tags:

```
<para>See the <link
  linkend="gmirror-troubleshooting"> Troubleshooting</link>
section if there are problems booting. Powering down and
disconnecting the original <filename> ada0</filename> disk
will allow it to be kept as an offline backup.</para>

<para>It is also possible to journal the boot disk of a &os;
system. Refer to the article <link
```

```
xlink:href="&url.articles.gjournal-desktop;"> Implementing UFS
Journaling on a Desktop PC</link> for detailed
instructions.</para>
```

When an element is too long to fit on the remainder of a line without wrapping, moving the start tag to the next line can make the source easier to read. In this example, the `systemitem` element has been moved to the next line to avoid wrapping and indenting:

```
<para>With file flags, even
  <systemitem class="username"> root</systemitem> can be
  prevented from removing or altering files.</para>
```

Configurations to help various text editors conform to these guidelines can be found in [Chapter 13, Editor Configuration](#).

12.3.4. Tag Style

12.3.4.1. Tag Spacing

Tags that start at the same indent as a previous tag should be separated by a blank line, and those that are not at the same indent as a previous tag should not:

```
<article lang='en'>
  <articleinfo>
    <title>NIS</title>

    <pubdate> October 1999</pubdate>

    <abstract>
      <para>...
    ...
  ...</para>
</abstract>
</articleinfo>

  <sect1>
    <title>...</title>

    <para>...</para>
  </sect1>

  <sect1>
    <title>...</title>

    <para>...</para>
  </sect1>
</article>
```

12.3.4.2. Separating Tags

Tags like `itemizedlist` which will always have further tags inside them, and in fact do not take character data themselves, are always on a line by themselves.

Tags like `para` and `term` do not need other tags to contain normal character data, and their contents begin immediately after the tag, *on the same line*.

The same applies to when these two types of tags close.

This leads to an obvious problem when mixing these tags.

When a starting tag which cannot contain character data directly follows a tag of the type that requires other tags within it to use character data, they are on separate lines. The second tag should be properly indented.

When a tag which can contain character data closes directly after a tag which cannot contain character data closes, they co-exist on the same line.

12.3.5. Whitespace Changes

Do not commit changes to content at the same time as changes to formatting.

When content and whitespace changes are kept separate, translation teams can easily see whether a change was content that must be translated or only whitespace.

For example, if two sentences have been added to a paragraph so that the line lengths now go over 80 columns, first commit the change with the too-long lines. Then fix the line wrapping, and commit this second change. In the commit message for the second change, indicate that this is a whitespace-only change that can be ignored by translators.

12.3.6. Non-Breaking Space

Avoid line breaks in places where they look ugly or make it difficult to follow a sentence. Line breaks depend on the width of the chosen output medium. In particular, viewing the HTML documentation with a text browser can lead to badly formatted paragraphs like the next one:

```
Data capacity ranges from 40 MB to 15
GB. Hardware compression ...
```

The general entity ` ` prohibits line breaks between parts belonging together. Use non-breaking spaces in the following places:

- between numbers and units:

```
57600&nbsp;bps
```

- between program names and version numbers:

```
&os;&nbsp;9.2
```

- between multiword names (use with caution when applying this to more than 3-4 word names like “The FreeBSD Brazilian Portuguese Documentation Project”):

12.4. Word List

This list of words shows the correct spelling and capitalization when used in FreeBSD documentation. If a word is not on this list, ask about it on the [FreeBSD documentation project mailing list](#).

Word	XML Code	Notes
CD-ROM	<code><acronym> CD-ROM </acronym></code>	
DoS (Denial of Service)	<code><acronym> DoS</acronym></code>	
email		
file system		
IPsec		
Internet		
manual page		
mail server		
name server		
Ports Collection		
read-only		
Soft Updates		
stdin	<code><varname> stdin</varname></code>	
stdout	<code><varname> stdout</varname></code>	
stderr	<code><varname> stderr</varname></code>	
Subversion	<code><application> Subversion</application></code>	Do not refer to the Subversion application as SVN in upper case. To refer to the command, use <code><command> svn</command></code> .
UNIX®	<code>&unix;</code>	
web server		

Chapter 13. Editor Configuration

Adjusting text editor configuration can make working on document files quicker and easier, and help documents conform to FDP guidelines.

13.1. Vim

Install from [editors/vim](#) or [editors/vim-lite](#).

13.1.1. Configuration

Edit `~/.vimrc`, adding these lines:

```
if has("autocmd")
  au BufNewFile,BufRead *.sgml,*.ent,*.xsl,*.xml call Set_SGML()
  au BufNewFile,BufRead *.[1-9] call ShowSpecial()
endif " has(autocmd)

function Set_Highlights()
  "match ExtraWhitespace /^\\s* \\s*\\|\\s\\+$/
  highlight default link OverLength ErrorMsg
  match OverLength /\\%71v.\\+ /
  return 0
endfunction

function ShowSpecial()
  setlocal list listchars=tab:>>,trail:*,eol:$
  hi def link nontext ErrorMsg
  return 0
endfunction " ShowSpecial()

function Set_SGML()
  setlocal number
  syn match sgmlSpecial "&[^;]*;"
  setlocal syntax=sgml
  setlocal filetype=xml
  setlocal shiftwidth=2
  setlocal textwidth=70
  setlocal tabstop=8
  setlocal softtabstop=2
  setlocal formatprg="fmt -p"
  setlocal autoindent
  setlocal smartindent
  " Rewrap paragraphs
  noremap P gqj
  " Replace spaces with tabs
```

```
noremap T :s/      /\t/<CR>
call ShowSpecial()
call Set_Highlights()
return 0
endfunction " Set_SGML()
```

13.1.2. Use

Press P to reformat paragraphs or text that has been selected in Visual mode. Press T to replace groups of eight spaces with a tab.

13.2. Emacs

Install from [editors/emacs](#) or [editors/xemacs](#).

Edit `~/.emacs`, adding these lines:

```
(defun local-sgml-mode-hook
  (setq fill-column 70
    indent-tabs-mode nil
    next-line-add-newlines nil
    standard-indent 4
    sgml-indent-data t)
  (auto-fill-mode t)
  (setq sgml-catalog-files '("/usr/local/share/xml/catalog")))
  (add-hook 'psgml-mode-hook
    '(lambda () (local-psgml-mode-hook))))
```

13.3. nano

Install from [editors/nano](#) or [editors/nano-devel](#).

13.3.1. Configuration

Copy the sample XML syntax highlight file to the user's home directory:

```
% cp /usr/local/share/nano/xml.nanorc ~/.nanorc
```

Add these lines to the new `~/.nanorc`.

```
syntax "xml" "\.([jrs]html?|xml|xslt?)"$"
# trailing whitespace
color ,blue "[[:space:]]+$"
# multiples of eight spaces at the start a line
# (after zero or more tabs) should be a tab
color ,blue "^[[:TAB]]*[ -]{8}+"
# tabs after spaces
color ,yellow "( )+TAB"
```

```
# highlight indents that have an odd number of spaces
color ,red "^([ -]{2})+|(TAB+))*[ -]{1}[^ -]{1}"
# lines longer than 70 characters
color ,yellow "^(.{71})|(TAB.{63})|(TAB{2}.{55})|(TAB{3}.{47}).+ $"
```

Process the file to create embedded tabs:

```
% perl -i'' -pe 's/TAB/\t/g' ~/.nanorc
```

13.3.2. Use

Specify additional helpful options when running the editor:

```
% nano -AKipwz -r 70 -T8 chapter.xml
```

Users of [csh\(1\)](#) can define an alias in `~/.cshrc` to automate these options:

```
alias nano "nano -AKipwz -r 70 -T8"
```

After the alias is defined, the options will be added automatically:

```
% nano chapter.xml
```

Chapter 14. See Also

This document is deliberately not an exhaustive discussion of XML, the DTDs listed, and the FreeBSD Documentation Project. For more information about these, you are encouraged to see the following web sites.

14.1. The FreeBSD Documentation Project

- [The FreeBSD Documentation Project web pages](#)
- [The FreeBSD Handbook](#)

14.2. XML

- [W3C's XML page SGML/XML web page](#)

14.3. HTML

- [The World Wide Web Consortium](#)
- [The HTML 4.0 specification](#)

14.4. DocBook

- [The DocBook Technical Committee](#), maintainers of the DocBook DTD
- [DocBook: The Definitive Guide](#), the online documentation for the DocBook DTD
- [The DocBook Open Repository](#) contains DSSSL stylesheets and other resources for people using DocBook

Appendix A. Examples

These examples are not exhaustive—they do not contain all the elements that might be desirable to use, particularly in a document's front matter. For more examples of DocBook markup, examine the XML source for this and other documents available in the Subversion doc repository, or available online starting at <http://svnweb.FreeBSD.org/doc/>.

A.1. DocBook `book`

Example A.1. DocBook `book`

```
<!DOCTYPE book PUBLIC "-//FreeBSD//DTD DocBook XML V5.0-Based &
